LEE-YANG ZEROS FOR DHL
AND 2D RATIONAL DYNAMICS,
I. FOLIATION OF THE PHYSICAL CYLINDER.

PAVEL BLEHER, MIKHAIL LYUBICH AND ROLAND ROEDER

Abstract. In a classical work of the 1950’s, Lee and Yang proved that the zeros of the partition functions of a ferromagnetic Ising models always lie on the unit circle. Distribution of these zeros is physically important as it controls phase transitions in the model. We study this distribution for the Migdal-Kadanoff Diamond Hierarchical Lattice (DHL). In this case, it can be described in terms of the dynamics of an explicit rational function \( R \) in two variables (the renormalization transformation). We prove that \( R \) is partially hyperbolic on an invariant cylinder \( C \). The Lee-Yang zeros are organized in a transverse measure for the central-stable foliation of \( R|C \). Their distribution is absolutely continuous. Its density is \( C^\infty \) (and non-vanishing) below the critical temperature. Above the critical temperature, it is \( C^\infty \) on a open dense subset, but it vanishes on the complementary Cantor set of positive measure. This seems to be the first occasion of a complete rigorous description of the Lee-Yang distributions beyond 1D models.

1. Introduction

1.1. Phenomenology of Lee-Yang zeros. The Ising model is designed to describe magnetic matter and, in particular, to explain the appearance of spontaneous magnetization in ferromagnets and transitions between ferromagnetic and paramagnetic phases as the temperature $T$ varies.

The matter in a certain scale is represented by a graph $\Gamma$. Let $\mathcal{V}$ and $\mathcal{E}$ stand respectively for the set of its vertices (representing atoms) and edges (representing magnetic bonds between the atoms).

A magnetic state of the matter is represented by spin configuration $\sigma : \mathcal{V} \to \{\pm 1\}$ on $\Gamma$. The spin $\sigma(v)$ represents a magnetic momentum of an atom $v \in \mathcal{V}$. The total magnetic momentum of the configuration is equal to

$$M(\sigma) = \sum_{v \in \mathcal{V}} \sigma(v).$$

Each configuration $\sigma$ has energy $H(\sigma)$ depending on the interactions $J(v, w)$ between the atoms and the external magnetic field $h(v)$. In the simplest isotropic case, $J$ and $h$ are constants, and the Hamiltonian assumes the form:

$$H(\sigma) = -J \sum_{\{v, w\} \in \mathcal{E}} \sigma(v)\sigma(w) - hM(\sigma),$$

where the first sum accounts for the energy of interactions between the atoms while the second one accounts to the energy of interactions of the matter with the external field.

By the Gibbs Principle, the spin configurations are distributed according to the Gibbs measure that assigns to configuration $\sigma$ a probability proportional to its Gibbs weight $W(\sigma) = \exp(-H(\sigma)/T)$, where $T$ is the temperature. Various observable magnetic quantities (e.g., magnetization $M$) are calculated by averaging of the corresponding functionals (e.g., $M(\sigma)$) over the Gibbs distribution.

The total Gibbs weight $Z = \sum W(\sigma)$ is called the partition function. It is a Laurent polynomial in two variables $(z, t)$, where $z = e^{-h/T}$ is a “field-like” variable and $t = e^{-J/T}$ is “temperature-like”\(^1\). For a fixed $t$, the complex zeros of $Z(z, t)$ in $z$ are called the Lee-Yang zeros. Their role comes from the fact that some important observable quantities can be calculated as electrostatic-like potentials of the equally charged particles located at the Lee-Yang zeros. (For instance, the free energy is equal to the logarithmic potential of such a family of particles.)

A celebrated Lee-Yang Theorem \[YL, LY\] asserts that for the ferromagnetic\(^2\) Ising model on any graph, for any real temperature $T > 0$, the Lee-Yang zeros lie on the unit circle $\mathbb{T}$ in the complex plane (corresponding to purely imaginary magnetic field $h = -iT\phi$).\(^3\)

---

\(^1\)We will often refer to them as just “field” and “temperature”.

\(^2\)i.e., with $J > 0$, which favors the same orientation of neighboring spins

\(^3\)We will take a liberty to use either $z$-coordinate or the angular coordinate $\phi = \arg z \in \mathbb{R}/2\pi\mathbb{Z}$ on $\mathbb{T}$ without a comment.
Magnetic matter in various scales can be modeled by a hierarchy of graphs $\Gamma_n$ of increasing size (corresponding to finer and finer scales of matter). For suitable models, the Lee-Yang zeros of the partition functions $Z_n$ will have an asymptotic distribution $d\mu_t = \rho_t d\phi/2\pi$ on the unit circle. This distribution supports singularities of the magnetic observables (or rather, their thermodynamical limits), and hence it captures phase transitions in the model. For instance, Lee and Yang showed that the spontaneous magnetization of the matter (as the external field vanishes) is equal to $\rho_t(0)$. So, the matter is ferromagnetic (meaning that it exhibits non-zero spontaneous magnetization) at temperature $t$ if and only if $\rho_t(0) > 0$.

The Lee-Yang zeros for the 1D Ising model with periodic boundary conditions (corresponding to the hierarchy of cyclic lattices $\Gamma_n = \mathbb{Z}/n\mathbb{Z}$) can be explicitly calculated using the transfer matrix technique (see e.g., [Ba]):

$$
\phi^\pm_k = \arccos \left[ \sqrt{1-t^4 \cos \left( \frac{\pi(k+1/2)}{n} \right)} \right]; \quad k = 0, 1, \ldots, n-1;
$$

(1.3)

see Appendix F. Their asymptotic distribution is supported on two symmetric intervals, $I^+ = [\phi^*, \pi - \phi^*]$ and $I^- = -I^+$, where $\cos \phi^* = \sqrt{1-t^4}$, and its density is equal to

$$
\rho_t(\phi) = \frac{|\sin \phi|}{2\pi \sqrt{1-t^4 - \cos^2 \phi}}.
$$

(1.4)

We see that for positive temperature, the support $I^+ \cup I^-$ does not contain point $\phi = 0$, and so the matter is paramagnetic and there are no phase transitions. As $T \to 0$ the gap between $I^+$ and $I^-$ closes up and the Lee-Yang zeros get equidistributed on the unit circle (so, in this model, the matter becomes ferromagnetic only at the zero-temperature limit). Note that $\rho_t$ is real-analytic on $I^\pm$ and has power-like singularities with exponent $(-1/2)$ at the end-points.

For the ferromagnetic Ising model on lattices $\mathbb{Z}^d$ with $d \geq 2$, a similar picture is believed to be true for high temperatures (above some critical temperature $T_c > 0$), while below $T_c$ the Lee-Yang distributions are conjectured to have full support with positive density. This scenario would lead to a second-order phase transition: a ferromagnet for $T < T_c$ turns into a paramagnet for $T > T_c$. However, these conjectures are hard to prove rigorously as no exact formulas for the Lee-Yang zeros are available.

For the two-dimensional lattice, the phase transitions can be rigorously justified by means of the Onsager exact solution, see [Ba]. In all dimensions $d > 1$, it was proven that for high temperatures, the Lee-Yang zeros do not accumulate on the point $\phi = 0$ (no spontaneous magnetization) [GMR, R1], while for low temperatures, they have positive density at $\phi = 0$ (the spontaneous magnetization is observed) [P, Gr]. However, unlike the one-dimensional Ising model, for sufficiently low temperatures, $\rho_t(\phi)$ is not real-analytic at $\phi = 0$ [Isa], see Remark 2.4.

In a recent breakthrough, it was proven in [BBCKK] that the Lee-Yang zeros $\phi^*_n(t) \in \mathbb{T}$ for the $\mathbb{Z}^d$ Ising model with periodic boundary conditions, $\Gamma_n = \mathbb{Z}^d/(n\mathbb{Z})^d$, can be calculated at sufficiently low temperature $t$ as

$$
\phi^*_n(t) = \pi k \left( \frac{\pi k}{2n^d} + \frac{\pi}{2n^d} \right) + O(\lambda^{-n}) \quad k = 0, 1, \ldots, 2n^d - 1
$$

(1.5)
where $\lambda > 1$ and $g_t(\phi)$ is a $C^2$-diffeomorphism of the circle smoothly depending on $t$. In particular, for sufficiently low temperatures, the limiting density $\rho_t(\phi)$ is $C^2$.

At high temperatures, a quantum field theory interpretation gives a prediction of the power exponents of the densities $\rho_t$ near the end-points of $I^\pm$, see Fisher [F1] and Cardy [Car]. For instance, for $d = 2$ the exponent is predicted to be $(-1/6)$, while for $d > 6$ it is predicted to be $1/2$.

Study of the Lee-Yang zeros is an active direction of research in contemporary statistical mechanics, see [MSH], [BB], [R4] and references therein for recent developments.

1.2. Diamond hierarchical model. The Ising model on hierarchical lattices was introduced by Berker and Ostlund [BO] and further studied by Bleher & Žalys [BZ1, BZ2, BZ3] and Kaufman & Griffiths [KG1]).

Let $\Gamma$ be an oriented graph with two vertices marked and ordered. The corresponding hierarchical lattice is a sequence of graphs $\Gamma_n$ with two marked and ordered vertices such that $\Gamma_0$ is an interval, $\Gamma_1 = \Gamma$, and $\Gamma_{n+1}$ is obtained from $\Gamma_n$ by replacing each edge of $\Gamma_n$ with $\Gamma$ so that the marked vertices of $\Gamma$ match with the vertices of $\Gamma_n$ and their order matches with the orientation of the corresponding edges of $\Gamma_n$. We then mark two vertices in $\Gamma_{n+1}$ so that they match with the two marked vertices of $\Gamma_n$.

For instance, the diamond hierarchical lattice (DHL) illustrated on Figure 1.1 corresponds to the diamond graph $\Gamma$.\footnote{In fact, in this case, we do not need to orient $\Gamma$ and order the marked vertices since the diamond is symmetric with respect to a reflection interchanging the marked vertices.}

Our paper is fully devoted to this lattice.

Remark 1.1. The definition of the total magnetic momentum that we will use for the DHL will be slightly different from (1.1) (see (2.1) and Appendix F.4 for a motivation). Also, we will use $t := t^2 = e^{-2J/T}$ for the temperature-like variable as it makes formulas nicer.

It was shown in [BZ3] that for any temperature $t \in [0,1]$, the Lee-Yang zeros for the Ising model on the DHL are dense on the unit circle. In this paper, we will describe the asymptotic distributions $d\mu_t = \rho_t d\phi/2\pi$ of the Lee-Yang zeros for various temperatures $t \in I = [0,1]$. These distributions are illustrated on Figure 1.2. It shows the cylinder $C = \mathbb{T} \times I$ in the angular coordinate $\phi \in [0,2\pi]$ on the circle $\mathbb{T}$. In the blue region the density $\rho_t$ of the Lee-Yang distributions is a positive $C^\infty$ function, while in the orange region it vanishes. We can see blue “tongues” going from the bottom to the top of the cylinder and orange “hairs”
sticking from the top. The tongues fill the cylinder densely. However, the hairs fill a set of positive area – in fact, of almost full area near the top. This creates a false impression that everything is orange near the top of Figure 1.2. One can also see that the lowest temperature is reached by hairs for zero field $h (\phi = 0)$: this is the critical temperature $t_c$ that separates the ferromagnetic and paramagnetic phases.

Here is a precise statement:

**Main Theorem (physical version).** For any temperature $t \in [0, 1)$ the limiting distribution $\mu_t(\phi)$ of the Lee-Yang zeros exists and it is absolutely continuous with respect to the Lebesgue measure on $T_t \equiv T \times \{ t \}$: $d\mu_t = \rho_t(\phi) d\phi$. It has the following properties:

1. For $0 \leq t < t_c$, the density $\rho_t(\phi)$ is a positive $C^\infty$ function on the circle $T_t$. Moreover, $\mu_0$ is the Lebesgue measure on $T_0$ (i.e., $\rho_0(\phi) \equiv 1$).
2. For $t = t_c$, the density $\rho_t(\phi)$ is a positive $C^\infty$ function on $T_{t_c} \setminus \{0, \pi\}$ with a power singularity at $\phi = 0, \pi$:

   $$\rho_t(\phi) \asymp |\phi|^\sigma \text{ near } 0, \quad \rho_t(\phi) \asymp |\phi - \pi|^\sigma \text{ near } \pi,$$

   with some exponent $\sigma = 0.064... \in (0, 1)$.
3. For $1 > t > t_c$, the density $\rho_t$ vanishes on a Cantor set $K_t \supset \{0, \pi\}$ of positive Lebesgue measure. Moreover, its measure tends to $2\pi$ as $t \to 1$.

   On each component of the complementary set $O_t = T_1 \setminus K_t$, the density $\rho_t$ is $C^\infty$.
4. For $t = 1$, the distribution $d\mu_t$ becomes purely atomic: it is supported on a countable dense subset of $T_1$.

Moreover, there is a family of homeomorphisms $g_t : T_0 \to T_t, t \in [0, 1)$, such that $g_t(\phi)$ is smooth in $t \in [0, 1)$ for any $\phi \in T$, $h_0 = \text{id}$, and $\rho_t = (g_t^{-1})'(\phi)$ a.e. on $T$.

For $t < t_c$, the family $g_t(\phi)$ is $C^\infty$ in two variables.
We see, in particular, that $\rho_t(0) > 0$ below $t_c$ and it vanishes above $t_c$, so we observe at $t_c$ the ferromagnetic-paramagnetic phase transition. However, unlike the scenario described above for the standard lattices, the Lee-Yang zeros do accumulate on $\phi = 0$ even in the paramagnetic phase $t > t_c$. So, though for $t > t_c$, the magnetization $M(\phi, t)$ vanishes at $\phi = 0$, it is not analytic nearby.

The distributions $\mu_t(\phi)$ described above for the $\mathbb{Z}^d$ and the DHL are examples of global distributions. One can obtain tangent distributions as follows. We fix an arbitrary point $\tilde{\phi}$ inside the support of $\mu_t(\phi)$ as a reference point and rescale the zeros near $\tilde{\phi}$, by the affine map $\phi \mapsto \frac{L_n}{2\pi} \rho_t(\tilde{\phi}) \cdot (\phi - \tilde{\phi}^n)$, where $L_n$ is the total number of Lee-Yang zeros at level $n$ and $\tilde{\phi}^n$ is the one that is closest to $\tilde{\phi}$. We say that the Lee-Yang zeros are locally rigid at $\tilde{\phi}$ if the rescaled zeros converge locally uniformly to the $\mathbb{Z}$ lattice, as $n \to \infty$.

It follows directly from (1.3) that the Lee-Yang zeros for the $\mathbb{Z}^1$ lattice are locally rigid everywhere. For the $\mathbb{Z}^d$ lattice (with periodic boundary conditions), infinitesimal rigidity follows at sufficiently low temperatures from (1.5), since $L_n = 2^n$.

Because there are $2 \cdot 4^n$ Lee-Yang zeros at level $n$ for the DHL, an expression of the form (1.5) is not sufficient to show their local rigidity. Instead, we will show that the LY zeros $\phi^n_k(t) \in \Omega_t$ can be expressed as $g^n_t(\phi^n_k(0))$, where the $g^n_t$ are diffeomorphisms locally $C^1$ converging to the maps $g_t$. This is sufficient for the local rigidity, see Proposition 13.1.

Below we will re-interpret the above results in terms of the renorm-group.

1.3. Migdal-Kadanoff RG equations. There is a general physical principle that the values of physical quantities depend on the scale where the measurement is taken. The corresponding quantities are called renormalized, and the (semi-group) of transformations relating them at various scales is called renorm-group (RG). However, it is usually hard to justify rigorously existence of RG, let alone to find exact formulas for RG transformations. The beauty of hierarchical models is that all this can actually be accomplished.

In [M1], [M2], Migdal suggested approximations to RG for the classical Ising model on $\mathbb{Z}^d$. They were further developed by Kadanoff [K], and became known as the Migdal-Kadanoff approximate RG equations. It was then noticed by Berker and Ostlund [BO] that these equations become exact for suitable hierarchical Ising models (see also [BZ1] and [KG1]). In particular, the DHL corresponds to the 2D lattice $\mathbb{Z}^2$. The Migdal-Kadanoff RG equations in this case assume the form:

\[
(z_{n+1}, t_{n+1}) = \left( \frac{z_n^2 + t_n^2}{z_n^2 + t_n^2}, \frac{z_n^2 + z_{n-2}^2 + 2}{z_n^2 + z_n^2 + t_n^2 + t_n^{-2}} \right) := R(z_n, t_n).
\]

where $z_n$ and $t_n$ are the renormalized field-like and temperature-like variables on $\Gamma_n$. The map $R$ that relates these quantities is also called the renormalization transformation.

The Lee-Yang zeros for $\Gamma_n$ are solutions of the algebraic equation $Z_n(z, t) = 0$, so they form a real algebraic curve $S_n$ on the cylinder $C$ (the Lee-Yang locus of level $n$), see Figure 1.3. Equation (1.7) shows that $S_n$ is the pullback of $S_0$ under the
Figure 1.3. The level $n$ Lee-Yang zeros $S_n$ for $n = 0, 1, 2$.

$n$-fold iterate of $R$, i.e., $S_n = (R^n)^* S_0$. In this way, the problem of asymptotical distribution of the Lee-Yang zeros is turned into a dynamical one.

1.4. Renormalization dynamics on the cylinder. The first observation is that the cylinder $C$ is $R$-invariant. Next, its bottom $B$ is $R$-invariant as well, and $R$ restricts to $z \mapsto z^4$ on $B$. Moreover, $B$ is superattracting, so there is an open basin $W^s(B)$ where the orbits converge to $B$: this is exactly the blue region on Figure 1.2.

The top $T$ of $C$ is also invariant except for two indeterminacy points $\alpha_{\pm} = (\pm \pi/2, 1)$ that “blow up” to a curve $G$ going across the cylinder (see Figure 3.3 below). Because of this phenomenon, the degree of $R$ on the top drops to 2, (namely, $R : z \mapsto z^2$ on $T$), and its basin $W^s(T)$ (roughly, the orange region on Figure 1.2) is not open, but rather a “Cantor bouquet” of hairs sticking from $T$.

Despite this, $R$ acts in a surprisingly nice way on the proper curves (i.e., curves connecting the bottom to the top) – namely, a proper curve in $C$ crossing $G$ only once lifts to four proper curves, compare Figure 1.3. In this sense, the action of $R$ on proper curves has degree four.

Our main dynamical result asserts that $R$ is partially hyperbolic on the cylinder $C_1 := C \setminus T$. This means that $R$ admits an invariant horizontal tangent cone field $K^h(x) \subset T_x C$ such that the horizontal tangent vectors $v \in K^h(x)$ get exponentially stretched under iterates of $R$.

Let us also consider the complementary vertical cone field $K^v(x) = T_x C \setminus K^h(x)$. A smooth curve $\gamma(t)$ in $C_1$ going through this cone field is called vertical. A vertical foliation on $C_1$ is a foliation whose leaves are proper vertical curves.

Given a vertical foliation $\mathcal{F}$, the holonomy transformations $g_t : B \to T \times \{t\}$, $t \in [0, 1)$, are defined by the property that $x$ and $g_t(x)$ belong to the same leaf of $\mathcal{F}$.

A central foliation for $R$ is an invariant vertical foliation.
Recall that a measurable map \( g : T \to T \) is called \textit{absolutely continuous} if preimages \( g^{-1}(X) \) of null-sets \( X \subset T \) are null-sets (where a \textit{null-set} means a set of zero Lebesgue measure). Note that this is not a symmetric notion: it may happen that a homeomorphism \( g \) is absolutely continuous while the inverse one, \( g^{-1} \), is not (and this is what actually happens below).

**Main Theorem (dynamical version).** The renormalization transformation \( R \) is partially hyperbolic on \( C^1 \), and it has a unique central foliation \( F^s \). This foliation is \( C^\infty \) on \( W^s(B) \) but is not absolutely continuous on \( W^s(T) \).

Given any proper vertical curve \( \gamma \) on \( C \), the pullback \((R^n)^* \gamma \) comprises \( 4^n \) proper vertical curves, and \((R^n)^* \gamma \to F \) exponentially fast (away from the top).

The basin \( W^s(B) \) is open and dense in \( C \). The basin \( W^s(T) \) has positive area, with density 1 at the top. The union of the two basins has full area in \( C \).

Our proof of this geometric result is based upon Counting Arguments (making use of Bezout’s Theorem). We call this method the “Enumerative Dynamics”.

A \textit{transverse invariant measure} \( \mu \) for \( F \) is a family of measures \( \mu_t, t \in [0,1) \), such that \( \mu_t = (g_t)_*(\mu_0) \). It is uniquely determined by \( \mu_0 \). The Lee-Yang distributions \( \mu_t \) form a transverse invariant measure for \( F \) equal to the Lebesgue measure on \( B \).

This fact makes a connection between the physical and dynamical versions of the Main Theorem that will allow us to derive (easily) the former from the latter.

Let us also mention that the dynamical picture described in the last part of the Main Theorem gives one more illustration of the “intertwined basins” phenomenon studied by Kan, Yorke et al [Kan, AYYK], and more recently by Bonifant and Milnor [BM].

In the upcoming Part II of this work, we will study the global structure of the renormalization transformation and zeros of the partition function (Lee-Yang-Fisher zeros) in the complex projective space \( \mathbb{CP}^2 \). The distribution of the zeros will be interpreted as the dynamical \((1,1)\)-current of \( R \), while the partition function itself will become the \textit{potential} of this current. In this way the classical Lee-Yang-Fisher Theory gets tightly linked to the contemporary Dynamical Pluripotential Theory.

1.5. **Structure of the paper.** Let us now outline the structure of the paper indicating ideas of the proofs. Since this paper is naturally placed on the borderline of three fields (statistical mechanics, dynamics, and complex geometry) we have attempted to make exposition reader-friendly for a non-expert in any one of these fields, by motivating the problems and supplying needed background and basic references.

We begin in §2 with relevant background material in statistical mechanics: description of the Ising model on graphs, formulation of the Lee-Yang Theorem, and comments on physical significance of the Lee-Yang zeros. In particular, we supply explicit formulas for the free energy and spontaneous magnetization in terms of the asymptotic distributions of these zeroes. Then we pass to the diamond hierarchical model and derive the Migdal-Kadanoff Renorm-Group (RG) Equations. They lead to the renormalization transformation \( R \).

In §3 we describe the structure of \( R \) on the invariant cylinder \( C \). It is strongly influenced by the presence of two indeterminacy points \( \alpha \pm = (\pm i, 1) \) on the top.

---

5Meaning that restrictions of the homeomorphism \( g_t^{-1} \) to \( W^s(B) \) are \( C^\infty \) but their restrictions to \( W^s(T) \) are not absolutely continuous.
that blow up to the curve $G$. (On Figure 1.2, these points are clearly seen as the tips of the two main tongues of the blue region.) Because of them, $R$ does not evenly cover the cylinder: the region below $G$ is covered four times while its complement is covered only twice. However, we show that $R$ acts properly with degree four on the space of proper vertical curves. We will derive from here by a Counting Argument the Lee-Yang Theorem for the DHL (§5).

In §4 we follow up this discussion with a description of the global features of $R$ on the complex projective space $\mathbb{CP}^2$: its critical and indeterminacy loci, superattracting fixed points and their separatrices. (In fact, here it is more convenient to deal with the map $R$ that comes directly from the Migdal-Kadanoff RG Equations, without passing to the “physical” $(z,t)$-coordinates. This map is semi-conjugate to $R$ by a degree two rational change of variable $\mathbb{CP}^2 \rightarrow \mathbb{CP}^2$.)

In §6 we prove that $R$ admits a horizontal invariant cone field $K^{\text{ah}}(x)$ on $C$. We construct it explicitly by taking the principal Lee-Yang locus $S \equiv S_0$ (which comprises two vertical segments) and translating it around the cylinder. It gives us two transverse vertical foliations on $C$. Then we define $K^{\text{ah}}(x)$ as the horizontal cone tangent to these foliations at $x$. Using Bezout’s Theorem, we check invariance of this cone field. Unfortunately, this cone field degenerates at the top. We partially fix this problem by modifying $K^{\text{ah}}(x)$ near the top in such a way that the new field $K^h(x)$ degenerates only at the indeterminacy points $\alpha_\pm$.

In §7 we prove that $R|C$ admits a dominated splitting. This means that there exists a “vertical” tangent line field $L^c(x)$ and constants $C > 0, \lambda > 1$ such that

\begin{equation}
\|DR^n(x) w\| \leq C\lambda^{-n}\|DR^n(x) v\| \quad \text{for any } x \in C \setminus U, \ w \in L^c(x), \ v \in K^h(x)
\end{equation}

(where $U$ is a neighborhood of the indeterminacy points), so the “horizontal” vectors get stretched exponentially faster than the “vertical” ones. Integrating the line field $L^c(x)$, we obtain an invariant family of smooth vertical curves filling in the whole cylinder. However, at this stage of the discussion we do not know yet that the integration is unique, so the integral curves may not form a foliation.

In §8 we prove our main dynamical result that the map $R|C$ is horizontally expanding (and thus partially hyperbolic). This means that under iterates the horizontal vectors get stretched exponentially fast:

\begin{equation}
\|DR^n(x) v\| \geq c\lambda^n\|v\|, \quad x \in C, \ v \in K^h(x),
\end{equation}

where $c > 0, \lambda > 1$. To establish this property, we consider a central projection $\pi$ in $\mathbb{CP}^2$ onto the line at infinity. By a Counting Argument, we show that $\pi \circ R^n$ restricted to the horizontal sections of the solid cylinder is a Blyschke product $B_n$ (in appropriate natural coordinates) vanishing at the origin to order $2^{n+2}$. Such a $B_n$ expands the circle metric at least by $2^{n+2}$, which gives us (1.9) with $\lambda = 2$. We then provide a second proof of this expanding property that exploits the combinatorics of the DHL partition functions and a variant of the Lee-Yang Theorem that we call the **LY Theorem with Boundary Conditions**.

In §9 we discuss the basin $W^s(B)$ of the bottom $B$ (the blue region of Figure 1.2). We explain where the tongues observed on this picture come from and prove that $W^s(B)$ supports a $C^\infty$ foliation, the stable foliation of $B$.

---

6This property is also referred to as **projective hyperbolicity** of $R$. 

---

Lee-Yang Zeros
In §10, we turn our attention to the top $\mathcal{T}$ of $\mathcal{C}$. We prove that its basin $\mathcal{W}^s(\mathcal{T})$ contains a comb of curves of positive measure. Moreover, the density of its slices by horizontal circles $\mathcal{T} \times \{t\}$ goes to 1 as $t \to 1$.

We then derive in §11, applying standard distortion techniques to horizontal curves, that almost any orbit on the cylinder converges either to the bottom $\mathcal{B}$ or to the top $\mathcal{T}$ (see [BloL] for the one-dimensional prototype of this method).

In the next section, §12, we use horizontal expansion to prove unique integrability of the invariant vertical line field $\mathcal{L}^c$ yielding the desired invariant central foliation $\mathcal{F}^c$. We then collect in §13 consequences about regularity of the the Lee-Yang distributions (as formulated above) and calculate various critical exponents.

In the last section, §14, we analyze smoothness of periodic leaves that terminate at periodic points on the top. Such leaves are real analytic near the bottom and the top, but we show that they must loose analyticity somewhere in the middle (in fact, generically they can have only finite smoothness). This is another manifestation of the phase transitions in this model.

We finish with several Appendices. In Appendix A we collect needed background in complex geometry: rational maps, indeterminacy points and their blow-ups, degrees and divisors.

In Appendix B we supply some calculations on the cylinder $\mathcal{C}$, particularly, near its top $\mathcal{T}$ and the indeterminacy points $\alpha_\pm$ (performing their “blow-ups” in various coordinates).

In Appendix C we construct an extension of $\mathcal{K}^h(x)$ that is invariant on an appropriate complex neighborhood of $\mathcal{C} \setminus \{\alpha_\pm\}$. It gives us a supply of complex horizontal curves that are used in §11 to obtain the Koebe distortion estimates.

In Appendix D we describe the global critical locus of the map $R$ in $\mathbb{CP}^2$.

In Appendix E we give a computational verification that $R|\mathcal{C}$ is horizontally expanding using the explicit formula for $R$. Formally speaking, this can substitute the conceptual proof of §8. However, this would not provide any insight into the nature of $\mathcal{R}$, neither could it be useful in another related situation.

In Appendix F we re-prove the classical Lee-Yang Theorem and extend it to the LY Theorem with Boundary Conditions used in §8. We then describe the Lee-Yang zeros in the one-dimensional model, and explain in what sense the hierarchical lattices give an approximation to the standard lattices $\mathbb{Z}^d$.

In Appendix G we collect several open problems. Finally, in Appendix H we provide a list of notation that are frequently used throughout the paper.

1.6. Basic notation and terminology. $\mathcal{I} = [0,1], \mathbb{C}^* = \mathbb{C} \setminus \{0\}, \mathcal{T} = \{|z| = 1\}, \mathbb{D}_r = \{|z| < r\}, \mathbb{D} = \mathbb{D}_1, \mathbb{D}^* = \mathbb{D} \setminus \{0\}, \mathbb{N} = \{0,1,2\ldots\}$.

Given two variables $x$ and $y$, $x \asymp y$ means that $c \leq |x/y| \leq C$ for some constants $C \gg c > 0$.

A path (in some topological space) is an embedded interval.

Acknowledgment. This project was designed by the first two authors in May 1991 during Pavel Bleher’s visit to the IMS at Stony Brook. It was resumed in the fall 2005 in Toronto during the Fields Institute Program on Renormalization in Dynamics and Mathematical Physics. The work of the first author is supported in part by the NSF grants DMS-0652005 and DMS-0969254. The work of the second author has been partially supported by NSF, NSERC and CRC funds.

We thank Robert Shrock for interesting discussions and comments. (In particular, formula (13.9) answers one of Shrock’s questions.)
2. Description of the model

2.1. Background: Ising models on graphs. Let $\Gamma$ be a graph representing a magnetic matter in a certain scale. Let $\mathcal{V}$ and $\mathcal{E}$ stand respectively for the set of its vertices (representing atoms) and edges (representing magnetic bonds between the atoms). Two vertices, $v$ and $w$, connected by an edge are called neighbors: we respectively write $(v, w) \in \mathcal{E}$ or $\{v, w\} \in \mathcal{E}$ for the corresponding oriented or unoriented edge, respectively.

A spin configuration on $\Gamma$ is a function $\sigma : \mathcal{V} \rightarrow \{\pm 1\}$. The spin $\sigma(v)$ represents a magnetic momentum of an atom $v \in \mathcal{V}$. The total magnetic momentum of the configuration is equal to

$$M(\sigma) = \frac{1}{2} \sum_{(v, w) \in \mathcal{E}} (\sigma(v) + \sigma(w)) = n_+(\sigma) - n_-(\sigma),$$

where $n_+(\sigma)$ and $n_-(\sigma)$ stand respectively for the number of $\{++\}$ and $\{-\}$ bonds.

The Ising model depends on three physical parameters:

- $J$ – the coupling constant (strength of the magnetic bonds between the atoms);
- $h$ – strength of the external magnetic field;
- $T$ – temperature.

The total energy of the configuration $\sigma$ is given by the Hamiltonian

$$H(\sigma) = -JI(\sigma) - hM(\sigma),$$

where

$$I(\sigma) := \sum_{\{v, w\} \in \mathcal{E}} \sigma(v)\sigma(w) = n_+(\sigma) + n_-(\sigma) - n_0(\sigma),$$

with $n_0(\sigma)$ being the number of $\{+\}$ bonds in $\sigma$.

Let $\text{Conf} = \text{Conf}(\Gamma)$ be the configuration space, i.e., the space of all spin configurations. The Gibbs weight of a configuration $\sigma$ is equal to

$$W(\sigma) \equiv W(\sigma; J/T, h/T) = e^{-H(\sigma)} = t^{-I(\sigma)/2} z^{-M(\sigma)},$$

where $z = e^{-h/T}$ and $t = e^{-2J/T}$ are field-like and temperature-like variables. In the physical ferromagnetic region we have $0 < z < \infty$, $0 < t < 1$. However, it is insightful to extend magnetic observables beyond this region. Let $\mathcal{P} = \{(z, t)\} \subset \mathbb{C}^2$ stand for a relevant parameter space.

The Gibbs weights are invariant under simultaneous change of sign of the external field and the spins:

$$W(-\sigma; J/T, -h/T) = W(\sigma; J/T, h/T).$$

This is the basic symmetry of the Ising model. It can be also formulated as follows. Consider the “total configuration space” $\hat{\text{Conf}} = \text{Conf} \times \mathcal{P}$ fibered over $\mathcal{P}$. The

---

7 As we have mentioned in the introduction, this definition is different from (1.1) as the summation here is taken over the bonds rather than the atoms: see Appendix F.4 for a motivation for this unconventional definition.

8 We let the Boltzmann constant $k = 1$. 

Gibbs weights \( W(\sigma; z, t) \) endow it with the fibered Gibbs measure. The basic symmetry translates into invariance of this measure under the involution
\[
\hat{\iota} : \text{Conf} \rightarrow \text{Conf}; \quad \hat{\iota} : (\sigma; z, t) \mapsto (-\sigma; z^{-1}, t).
\]

The partition function (or the statistical sum) is the total Gibbs weight of the space:
\[
Z_\Gamma = Z_\Gamma(z, t) = \sum_{\sigma \in \text{Conf}} W(\sigma).
\]
It is a Laurent polynomial in \( z \) and \( t \). Moreover, as a consequence of the basic symmetry, \( Z_\Gamma \) is invariant under the involution \( \hat{\iota} : (z, t) \mapsto (z^{-1}, t) \), so it has a form
\[
Z_\Gamma = \sum_{n=0}^{d} a_n(t)(z^n + z^{-n}), \quad \text{where } d = |E|.
\]
Moreover, \( a_d = t^{-d/2} \). Thus, for any given \( t \in \mathbb{C}^* \), \( Z_\Gamma(t, z) \) has \( 2|E| \) roots \( z_i(t) \in \mathbb{C} \). They are called Lee-Yang zeros.

The Gibbs distribution is the probability measure on Conf with probabilities of the configurations proportional to the Gibbs weights:
\[
P(\sigma) = \frac{W(\sigma)}{Z}.
\]
Note that it gives a bigger weight to less energetic configurations.

The entropy of a configuration \( \sigma \) is defined as \( S(\sigma) = -\log P(\sigma) = \log Z + H(\sigma)/T \). The free energy is defined as
\[
F_\Gamma = H(\sigma) - TS(\sigma) = -T \log Z_\Gamma.
\]
It is independent of the configuration \( \sigma \) (in the Gibbs state) and hence coincides with its average over Conf.

**Remark 2.1.** One can define in the same way the entropy and the free energy for an arbitrary probability distribution on Conf. Then the Gibbs distribution is singled out by one of two equivalent properties: (i) it minimizes the free energy; (ii) the free energy is evenly distributed over configurations.

Equations (2.6) and (2.5) imply:
\[
F_\Gamma = -T \sum \log |z - z_i(t)| + |E| T \left( \log |z| + \frac{1}{2} \log |t| \right)
\]
where the summation is taken over the \( 2|E| \) Lee-Yang zeros \( z_i(t) \) of \( Z(\cdot, t) \) (here \( \log |z| \) - and \( \log |t| \)-terms account respectively for the denominator and the leading coefficient of \( Z(\cdot, t) \)).

**Remark 2.2.** In the physical region, the variables \( z \), \( t \) and \( Z \) are positive, so no absolute values are needed in (2.7). They are introduced in order to extend \( F_\Gamma \) to the complex plane in such a way that \( F_\Gamma - |E| T \log |z| \) is superharmonic. We will still refer to this extension as the “free energy”.

The magnetization of the matter is the average of the the magnetic momentum over the Gibbs distribution:
\[
M_\Gamma = \sum M(\sigma) P(\sigma) = -z \frac{\partial F_\Gamma}{\partial h} = -z \sum \frac{1}{z - z_i} + |E|.
\]

**Remark 2.3.** Note that this expression gives a meromorphic continuation of \( M_\Gamma \) to the complex plane. It will still be referred as the “magnetization”.

The Ising model is called ferromagnetic if \( J > 0 \), and anti-ferromagnetic otherwise. The Gibbs distribution of a ferromagnetic model favors neighboring spins with the same orientation.

Notice that for a ferromagnetic model, \( t = e^{-J/T} \in [0, 1] \), where \( t = 0 \) and \( t = 1 \) correspond respectively to zero and infinite temperature.

**Lee-Yang Theorem** ([YL, LTY]). For a ferromagnetic Ising model, for any temperature \( t \in (0, 1) \), the Lee-Yang zeros \( z_i(t) \) lie on the unit circle \( \mathbb{T} \).

This is a fundamental theorem of statistical mechanics. In Appendix F we will provide a proof of it in this general form (in fact, even in a slightly more general one). In §5 we will prove it for DHL using dynamics of the Migdal-Kadanoff renormalization.

Given a subsystem of atoms, \( U \subseteq V \), and a partial configuration \( \sigma_U : U \rightarrow \{ \pm 1 \} \), we can define conditional configurations as all configurations \( \sigma : V \rightarrow \{ \pm \} \) that agree with \( \sigma_U \) on \( U \). Let \( \text{Conf}(\Gamma|\sigma_U) \) stand for the space of all such configurations. The conditional partition function is defined as the total weight of this space:

\[
Z_{\Gamma|\sigma_U} = \sum_{\sigma \in \text{Conf}(\Gamma|\sigma_U)} W(\sigma).
\]

**Lee-Yang Theorem with Boundary Conditions.** Consider a ferromagnetic Ising model on a connected graph \( \Gamma \) and let \( \sigma_U \equiv 1 \) on a nonempty \( U \subseteq V \). Then, for any temperature \( t \in (0, 1) \) the Lee-Yang zeros \( z_i^+(t) \) of the conditional partition function \( Z_{\Gamma|\sigma_U} \) lie outside the closed disc \( \overline{D} \).

This interpretation follows directly from the proof of the classical Lee-Yang Theorem; see Appendix F. From the Basic Symmetry of the Ising model we get that for \( \sigma_U \equiv -1 \) and \( t \in (0, 1) \) the Lee-Yang zeros \( z_i(t) \) lie in the open disc \( D \).

### 2.2. Multiplicativity of the partition function.

For a subgraph \( \Gamma' \subset \Gamma \), let \( \Gamma' \) stand for its closure obtained by adding to \( \Gamma' \) all of the vertices adjacent to \( \Gamma' \) and all of the edges connecting them to \( \Gamma' \). Let \( \partial \Gamma' = \Gamma' \setminus \Gamma \).

**Lemma 2.1.** Let \( \sigma_U \) be a conditional configuration and let \( \Gamma_i \) be the connected components obtained after removing the vertices \( U \) and all of the edges ending at them from \( \Gamma \). Then

\[
Z_{\Gamma|\sigma_U} = \prod_i Z_{\Gamma_i|\sigma_{\partial \Gamma_i}}.
\]

**Proof.** Clearly,

\[
\text{Conf}(\Gamma|\sigma_U) \approx \prod_i \text{Conf}(\Gamma_i|\sigma_{\partial \Gamma_i}).
\]

Since there are no interactions between the partial configurations \( \sigma|\Gamma_i \), we have the additivity property for the energy:

\[
H(\sigma|\sigma_U) = \sum H(\sigma_{\Gamma_i}|\sigma_{\partial \Gamma_i}).
\]

This implies multiplicativity for the corresponding Gibbs weights and (together with (2.9)) for the conditional partition functions. \( \square \)
2.3. **Thermodynamic limit.** For finite graphs, the partition function $Z$ is a Laurent polynomial with non-negative coefficients, so the free energy $F = -T \log Z$ is real analytic in the physical region – there are no phase transitions. To observe phase transitions, one should pass to a thermodynamic limit. Already in the original paper by Lee & Yang [LY], the phase transitions were explicitly related to the asymptotic distribution of the zeros of the partition functions. In this section we will give a more rigorous account of these classical results.

Assume that we have a “lattice” given by a “hierarchy” of graphs $\Gamma_n$ of increasing size (corresponding to finer and finer scales of the matter)\(^9\) with partition functions $Z_n$, free energies $F_n$ and magnetizations $M_n$. To pass to the thermodynamic limit we normalize these quantities per bond.\(^10\) Let us say that our hierarchy of graphs has a thermodynamic limit if

$$\frac{1}{|E_n|} F_n(z, t) \to F(z, t) \quad \text{for any } z \in \mathbb{R}_+, \ t \in (0, 1).$$

In this case, the function $F$ is called the free energy of the lattice.

**Proposition 2.2.** Assume that a hierarchy of graphs has a thermodynamic limit. Then for any $t \in (0, 1)$, the limit (2.10) in $z$ exists in $L^1_{\text{loc}}(\mathbb{T})$ and the zeros of the partition functions $Z_n$ are asymptotically equidistributed with respect to some measure $\mu_t$ on the unit circle $\mathbb{T}$. Moreover, the limiting free energy $F(z, t)$ admits the following electrostatic representation:

$$F(z, t) = -2T \int_{\mathbb{T}} \log |z - \zeta| \, d\mu_t(\zeta) + T(\log |z| + \frac{1}{2} \log |t|) \quad \text{for a.e. } z \in \mathbb{C},$$

so $F(z, t) - T \log |z|$ is superharmonic in $z$ on the whole plane $\mathbb{C}$, and is harmonic on $\mathbb{C} \setminus \text{supp} \mu_t$.

Furthermore, the magnetizations $\frac{1}{|E_n|} M_n$ converge locally uniformly on $\mathbb{C} \setminus \text{supp} \mu_t$, and the limiting magnetization $M$ admits the following Cauchy integral representation:

$$M(z, t) = -\frac{\partial F}{\partial h} = -2z \int_{\mathbb{T}} \frac{d\mu_t(\zeta)}{z - \zeta} + 1 \quad \text{for } z \in \mathbb{C} \setminus \text{supp} \mu_t,$$

so $M(z, t)$ is holomorphic in $z$ on $\mathbb{C} \setminus \text{supp} \mu_t$.

**Proof.** We will fix some $t \in (0, 1)$ and will consider all the functions in $z$-variable only. Let $z^n$ stand for the zeros of the $Z_n$. Let us clear up the denominators of the Laurent polynomials $Z_n$ to obtain ordinary polynomials $\tilde{Z}_n = z^{d_n} Z_n$ (where $d_n = |E_n|$). They have the same zeros as the $Z_n$, so by the Lee-Yang Theorem, they do not vanish on $\mathbb{D}$. Hence they admit well defined roots $\phi_n := \tilde{Z}_n^{1/d_n}$ on $\mathbb{D}$ that are positive on the real line.

Since the polynomials $\tilde{Z}_n$ have positive coefficients, we have:

$$|\phi_n(z)| \leq \phi_n(1) \leq \exp \left\{ -\frac{1}{T d_n} F_n(1) \right\} \leq C \quad \text{for any } z \in \mathbb{D},$$

where the last bound follows from existence of the thermodynamic limit.

---

\(^9\)At this moment, the terms “lattice” and “hierarchy” are used in a purely heuristic sense. Formally speaking, we just have a sequence of graphs with $|\Gamma_n| \to \infty$.

\(^10\)Viewing $|E|$ as the “volume” of the system, the normalized quantities get interpreted as “specific” free energy and magnetization.
By Montel’s Theorem, the sequence of functions \( \phi_n \) is normal on \( \mathbb{D} \). Since it converges on \((0,1)\), it converges locally uniformly on \( \mathbb{D} \) to a holomorphic function \( \phi \). Hence the free energies \( d_n^{-1}F_n = -T(\log |\phi_n| - \log |z|) \) converge locally uniformly on \( \mathbb{D}^* \) to the harmonic function \( F := -T(\log |\phi| - \log |z|) \).

By the basic symmetry \( z \mapsto 1/z \), we have \( d_n^{-1}F_n \to F \) locally uniformly on \( \mathbb{C} \setminus \mathbb{D} \). Moreover, by the same symmetry and \( (2.13) \), the functions \( d_n^{-1}F_n \) are uniformly bounded from above globally on \( \mathbb{C} \). By the Compactness Theorem for superharmonic functions (see [Ho, Thm 4.1.9]), the function \( F \) admits a superharmonic extension to the whole plane \( \mathbb{C} \) and

\[
(2.14) \quad \frac{1}{d_n}F_n \to F \text{ in } L^1_{\text{loc}}(\mathbb{C}).
\]

Let \( \delta_z \) stand for the unit mass located at \( z \), and let \( \mu^n \equiv \mu^n_t = \frac{1}{2\pi i} \sum \delta_z^n \).

Since \( \frac{1}{2\pi} \log |\zeta| \) is the fundamental solution of the Laplace equation, \((2.7)\) implies that

\[
(2.15) \quad -\frac{1}{4\pi T} \frac{\Delta F_n}{d_n} = \frac{1}{2d_n} \sum \delta_z^n - \frac{1}{2} \delta_0,
\]

where the Laplacian \( \Delta \) is understood in the sense of distributions.

Since the distributional Laplacian is a continuous operator, \((2.14)\) implies that \( d_n^{-1}\Delta F_n(\cdot,t) \to \Delta F(\cdot,t) \) in the weak topology on the space of measures. Together with \((2.15)\), this implies that the Lee-Yang zeros are equidistributed with respect to measure

\[
\mu \equiv \mu_t := -\frac{1}{4\pi T} \Delta F(\cdot,t) + \frac{1}{2} \delta_0.
\]

Let \( u^n(z) \equiv u^n_t(z) \) and \( u(z) \equiv u_t(z) \) stand for the electrostatic potentials of \( \mu^n \) and \( \mu \) respectively. For \( z \in \mathbb{C} \setminus \mathbb{T} \), the kernel \( \zeta \mapsto \log |z - \zeta| \) is a continuous function on \( \mathbb{T} \) depending continuously (in the uniform topology) on \( z \). It follows that \( u^n(z) \to u(z) \) locally uniformly on \( \mathbb{C} \setminus \mathbb{T} \). But by \((2.7)\),

\[
\frac{1}{d_n}F_n = -2T u^n(z) + T(\log |z| + \frac{1}{2} \log |t|).
\]

Since \((2.14)\) implies that for some subsequence \( n_k \), \( \frac{1}{|d_{n_k}|}F_{n_k}(z) \to F(z) \) a.e., representation \((2.11)\) follows.

Taking its \( \partial/\partial h \)-derivative (where \( h = -T \log z \)), we obtain representation \((2.12)\). \( \square \)

The basic symmetry of the Ising model implies that the free energy is an even function of the field \( h \), while the magnetization is odd. In terms of the \((z,t)\)-variables, \( F \) & \( M \) are respectively even & odd under the involution \( \iota \) (which is also clear from explicit representations \((2.11)\) and \((2.12)\)). If the magnetization has different limits at \( z = 1 \) from above and below, \( M^+(1) > 0 \) and \( M^-(1) = -M^+(1) < 0 \), then one says that the first order phase transition occurs (at \( h = 0 \)), and call \( M^+(1) \) the spontaneous magnetization of the model. The following statement makes physical relevance of the Lee-Yang zeros particularly clear:

**Corollary 2.3.** Assume the distribution \( \mu_t \) is absolutely continuous on the unit circle and its density \( \rho_t(\phi) = 2\pi d\mu_t(\phi)/d\phi \) is Hölder continuous at \( \phi = 0 \). Then
the first order phase transition at \( h = 0 \) occurs if and only if \( \rho(1) \neq 0 \), and the corresponding spontaneous magnetization \( M^+(1) \) is equal to \( \rho(0) \).

**Proof.** Formula (2.12) with \( d\mu_t = \rho_t d\phi/2\pi \) can be also written as follows:

\[
M(z, t) = -2 \left( \frac{1}{2\pi i} \int_T \frac{\rho_t(\zeta)}{\zeta - z} d\zeta - \frac{1}{2\pi i} \int_T \frac{\rho_t(\zeta)}{\zeta} d\zeta \right) - 1.
\]

By the Sokhotsky Theorem (see [Kre, Theorem 7.6]), the jump at \( z = 1 \) (from inside to outside of \( T \)) of the Cauchy integral in parentheses is equal to \( \rho(1) \). Hence the jump of \( M \) (from inside to outside) is equal to \(-2\rho(1)\). On the other hand, it is equal to \(-2M^+(0)\).

**Remark 2.4.** If the limiting distribution \( \mu_t \) has a density \( \rho_t(\phi) \) that is real-analytic in a neighborhood of \( \phi = 0 \), then (2.11) allows for a analytic continuation of \( F(z, t) \) in a neighborhood of \( z = 1 \) by a deformation of contours.

For the \( \mathbb{Z}^d \) Ising model, \( d > 1 \), Isakov [Isa] has shown that no such analytic continuation exists at sufficiently low temperatures. Thus, for these models \( \rho_t(\phi) \) cannot be real-analytic \( \phi = 0 \) for low temperatures.

### 2.4. Diamond Hierarchical Lattice (DHL) and Migdal-Kadanoff renormalization

Let us start with the simplest possible graph \( \Gamma_0 \): just two vertices, \( a \) and \( b \), connected with one edge. The space \( \text{Conf}_{\Gamma_0} \) consists of four configurations with the following energies:

\[
H \left( \begin{array}{c|c} + & \oplus \\ \hline \ominus & \ominus \end{array} \right) = -J - h, \quad H \left( \begin{array}{c|c} + & \ominus \\ \hline \ominus & + \end{array} \right) = J, \quad H \left( \begin{array}{c|c} \oplus & \ominus \\ \hline \ominus & \ominus \end{array} \right) = -J + h,
\]

and the following Gibbs weights:

\[
U = W \left( \begin{array}{c} + \\ \hline \ominus \end{array} \right) = z^{-1} t^{-1/2},
\]

\[
V = W \left( \begin{array}{c} + \\ \hline + \end{array} \right) = W \left( \begin{array}{c} \ominus \\ \hline \ominus \end{array} \right) = t^{1/2},
\]

\[
W = W \left( \begin{array}{c} \ominus \\ \hline \ominus \end{array} \right) = z t^{-1/2}.
\]

They sum up to the following partition function:

\[
Z \equiv Z_{\Gamma_0} = U + 2V + W = \frac{z^2 + 2tz + 1}{z \sqrt{t}}.
\]

Let us now replace the interval \( \Gamma_0 \) with a diamond \( \Gamma_1 \) with vertices \( a, b, c, d \) (so that it shares with \( \Gamma_0 \) the vertices \( a \) and \( b \)), see Figure 1.1. Restricting that the spins at \( a \) and \( b \) are both + and summing over the four spin configurations \((+, +) \) \((-+, +) \) & \((+, -) \), and \((-+, -) \) at the vertices \( c \) and \( d \) yields a sum of four conditional partition functions (two of which are equal):

\[
U_1 := Z_{\Gamma_1|++} = U^4 + 2U^2V^2 + U^4 = (U^2 + V^2)^2.
\]

Similarly

\[
V_1 := Z_{\Gamma_1|+-} = Z_{\Gamma_1|-+} = U^2V^2 + 2UV^2W + V^2W^2 = V^2(U + W)^2,
\]

\[
W_1 := Z_{\Gamma_1|--} = V^4 + 2V^2W^2 + W^4 = (W^2 + V^2)^2.
\]

The full partition function of \( \Gamma_1 \) is equal \( Z_{\Gamma_1} = U_1 + 2V_1 + W_1 \).
Replacing each edge of the diamond with $\Gamma_1$, we obtain a lattice $\Gamma_2$ with 16 edges. Inductively, replacing each edge of the diamond with the lattice $\Gamma_{n-1}$, we obtain the lattice $\Gamma_n$ with $4^n$ edges, \(^{11}\) see Figure 2.1.

All lattices $\Gamma_n$ share four vertices, $a$, $b$, $c$ and $d$, with the original diamond. Restricting the spins at $\{a, b\}$ we obtain three conditional partition functions, $U_n$, $V_n$ and $W_n$ as follows:

\[
\begin{align*}
U_n := Z_n \left( \begin{array}{c}
\oplus \otimes \otimes \ominus
\end{array} \right), \\
V_n := Z_n \left( \begin{array}{c}
\oplus \otimes \ominus \ominus
\end{array} \right), \\
W_n := Z_n \left( \begin{array}{c}
\ominus \otimes \ominus \oplus
\end{array} \right)
\end{align*}
\]

The total partition function is equal to

\[Z_n = Z_{\Gamma_n} = U_n + 2V_n + W_n.\]

Similarly to the above formulas for $U_1$, $V_1$ and $W_1$, we have:

**Migdal-Kadanoff RG Equations:**

\[
\begin{align*}
U_{n+1} &= (U_n^2 + V_n^2)^2, \\
V_{n+1} &= V_n^2(U_n + W_n)^2, \\
W_{n+1} &= (V_n^2 + W_n^2)^2.
\end{align*}
\]

\(^{11}\)This description of the DHL is “dual” to the one given in the Introduction, §1.2.
\( U_{n+1} = Z_{n+1} \)

\[ = Z_{n+1} \left( \begin{array}{c}
\oplus \\
\oplus \\
\oplus \\
\oplus
\end{array} \right) + 2Z_{n+1} \left( \begin{array}{c}
\oplus \\
\oplus \\
\oplus \\
\oplus
\end{array} \right) + Z_{n+1} \left( \begin{array}{c}
\oplus \\
\oplus \\
\oplus \\
\oplus
\end{array} \right) \]

\[ = U_n^4 + 2U_n^2V_n^2 + V_n^4. \]

Figure 2.2. Derivation of the Migdal-Kadanoff Equations.

\((U_n, V_n, W_n) = R^n(U, V, W)\). The full partition function is obtained by the \( R^n \)-

pullback of the linear form \( Z = U + 2V + W \):

\[ Z_n = Z \circ R^n. \]

The renormalization operator \( R \) descends to a rational transformation \( R : \mathbb{CP}^2 \rightarrow \mathbb{CP}^2 \). In the affine coordinates \( u = U/V, w = W/V \), it assumes the form:

\[ R : (u, w) \mapsto \left( \frac{u^2 + 1}{u + w}, \frac{w^2 + 1}{u + w} \right)^2, \]

where the external squaring stands for the squaring of both coordinates, \((u, w)^2 = (u^2, w^2)\). According to (2.16), these coordinates are related to the “physical” \((z, t)\)-coordinates as follows:

\[ (u, w) = \Psi(z, t) = \left( \frac{1}{zt}, \frac{z}{t} \right). \]

In \((z, t)\)-coordinates, the renormalization transformation assumes the form:

\[ \mathcal{R} : (z, t) \mapsto \left( \frac{z^2 + t^2}{z^2 - 2 + t^2}, \frac{z^2 + z^{-2} + 2}{z^2 + z^{-2} + t^2 - t^{-2}} \right). \]

The iterates \((z_n, t_n) = \mathcal{R}^n(z, t)\) are related to \((U_n, V_n, W_n)\) by means of (2.16):

\[ U_n = z_n^{-1} t_n^{-1/2}, \text{ etc.} \]

Physically, they are interpreted as the renormalized field-like and temperature-like variables.

2.5. Basic Symmetries. By the basic symmetry of the Ising model, the change of sign of \( h \) interchanges the conditional partition functions \( U_n \) and \( W_n \) keeping \( V_n \) and the total sum \( Z_n \) invariant. Consequently, the RG transformation \( R \) commutes with the involution \((U, V, W) \mapsto (W, V, U)\), which is also obvious from the explicit formula (2.18). Accordingly, the transformation \( R \) commutes with the permutation \((u, w) \mapsto (w, u)\), while \( \mathcal{R} \) commutes with \((z, t) \mapsto (z^{-1}, t)\).

All these transformations have real coefficients, so all of them commute with the corresponding complex conjugacies: \((U, V, W) \mapsto (\bar{U}, \bar{V}, \bar{W}), \text{ etc.} \)

Finally, there is an extra “accidental” symmetry of the DHL: the generating diamond \( \Gamma_1 \) is symmetric under reflection across the vertical axis. It results in the
squared terms in the Migdal-Kadanoff RG Equations that makes the LY distributions \( \mu_t \) symmetric under the half-period translation \( \phi \mapsto \phi + \pi \). It will play an important role in §8.2.

3. STRUCTURE OF THE RG TRANSFORMATION I: INVARIANT CYLINDER

We will now begin to explore systematically the RG dynamics. Its generator was represented above in several coordinate systems, in particular, as a transformation \( R \) (2.20) in the affine coordinates \((u, w)\) and as a transformation \( \mathcal{R} \) (2.22) in the physical coordinates \((z, t)\). From a physical point of view we are primarily interested in the latter. However, \( R \) possess better global dynamical properties. For these reasons we will treat both mappings in parallel.

Since \( R \) and \( \mathcal{R} \) represent the same map in different coordinates, the corresponding change of variables (2.21) should be equivariant, i.e., the following diagram must commute:

\[
\begin{array}{ccc}
\mathbb{CP}^2 & \xrightarrow{\mathcal{R}} & \mathbb{CP}^2 \\
\downarrow \Psi & & \downarrow \Psi \\
\mathbb{CP}^2 & \xrightarrow{R} & \mathbb{CP}^2
\end{array}
\]

(3.1)

wherever the maps are well defined. And this is indeed true and can be verified directly using the explicit formulas for the maps.

In this section we will describe basic features of \( \mathcal{R} \) (viewed statically) on the invariant cylinder (that supports the Lee-Yang zeros) and of \( R \) on the corresponding invariant Möbius band.

3.1. INVARIANT CYLINDER AND MÖBIUS BAND. Let us consider the round cylinder \( \mathcal{C} = T \times I \) naturally sitting in \( \mathbb{C}^2 \). It is obvious from (2.22) that \( \mathcal{C} \) is invariant under \( \mathcal{R} \).

**Remark 3.1.** Note that the whole bi-infinite cylinder \( \hat{\mathcal{C}} = T \times \mathbb{R} \) is also invariant under \( \mathcal{R} \), and in fact, \( \mathcal{R}(\hat{\mathcal{C}}) \subset \mathcal{C} \). (Here the upper cylinder \((t > 1)\) corresponds to the anti-ferromagnetic region.)

We keep identifying the unit circle \( T \) with \( \mathbb{R}/2\pi\mathbb{Z} \), so that points \((z, t) \ (z \in T)\) of the cylinder \( \mathcal{C} \) will often be written in the angular coordinate as \((\phi, t)\), where \( z = e^{i\phi}, \phi \in \mathbb{R}/2\pi\mathbb{Z} \). Let \( T_t = T \times \{\phi\} \) be the horizontal sections of the cylinder.

We will use special notation for the bottom and the top sections:

\[
B = T_0 \quad T = T_1.
\]

We will also use special notation \( C_1 := \mathcal{C} \setminus T \) and \( C_0 := \mathcal{C} \setminus B \) respectively for the topless and the bottomless cylinder.

The cylinder is foliated by the vertical intervals

\[
I_\phi = \{(\phi, t) : 0 \leq t \leq 1\}.
\]

The interval \( I_0 = \{\phi = 0\} \) plays a distinguished role, both physically and dynamically. Physically, it corresponds to the vanishing magnetic field. Dynamically, it is singled out by the property of being invariant under \( \mathcal{R} \). Its endpoints \( \beta_0 = (0, 0) \in B \) and \( \beta_1 = (0, 1) \in T \) are superattracting fixed points for \( \mathcal{R}|_{I_0} \), and there is a unique repelling fixed point \( \beta_c = (0, t_c) \in I_0 \). This is exactly the critical
point of the Ising model\textsuperscript{12} mentioned in the introduction and marked on Figure 1.2. All points $\beta \in I_0$ below $\beta_c$ converge to $\beta_0$, while all points above it converge to $\beta_1$.

Let us now switch to the affine coordinates $(u, w) = \Psi(z, t)$ from (2.21). Consider a topological annulus

\begin{equation}
C_0 = \{ (u, w) \in \mathbb{C}^2 : w = \bar{u}, \ |u| \geq 1 \}.
\end{equation}

in $\mathbb{C}^2$, and let $C$ stand for its closure in $\mathbb{C} \mathbb{P}^2$. Let $T = \{ (u, \bar{u}) : |u| = 1 \}$ be the “top” circle of $C$, while $B$ be the slice of $C$ at infinity.

Though the change of variables $\Psi$ is not globally invertible, it is nearly such on the cylinder $C$:

**Proposition 3.1.**

(i) $\Psi$ restricts to a diffeomorphism $C_0 \to C_0$;

(ii) $C = \Psi(C)$ is an $R$-invariant Möbius band, and $B$ is an $R$-invariant circle, a "median" of the band (given as the unit circle in the coordinate $\zeta = w/u$).

(iii) $R$ acts on $C_0$ as $u \to \left( \frac{u^2 + 1}{2 \text{Re} u} \right)^2$, and it acts on $B$ as $\zeta \mapsto \zeta^4$;

(iv) The map $\Psi : B \to B$ is 2-to-1, and $\Psi : C \to C$ continuously semiconjugates $R$ to $R$.

\textbf{Proof.} It is obvious from (2.21) that $\Psi$ maps $C_0$ smoothly to $C_0$. Moreover, $(\phi, t)$ can be recovered from $(u, v) = \Psi(\phi, t)$ as the polar coordinates of $u^{-1} = te^{i\phi}$. This yields (i).

Let us use coordinates $(\xi = 1/u, \zeta = w/u)$ near the line at infinity $\{ \xi = 0 \}$. In these coordinates, the map $\Psi$ assumes the form $\xi = tz$, $\zeta = z^2$, which makes obvious its continuity. Hence it maps $C$ onto $C$.

Moreover, the circle $B$ is mapped to the circle $B = \{ \xi = 0, |\xi| = 1 \}$ by $\zeta = z^2$. So, topologically $C$ is obtained from the cylinder $C$ by identifying the antipodal points $z$ and $-z$ on $B$. This makes the Möbius band.

Invariance of $C$ and $B$ follow from the semi-conjugacy or directly from (2.20). Expressions (iii) are also straightforward. \hfill $\Box$

In the coordinate $u$ on $C$, the interval $I_0$ becomes the real ray $I_0 = \{ u \in \mathbb{R}, u \geq 1 \}$ and the fixed points $\beta_1, \beta_c, \beta_0$ on $I_0$ become fixed points $b_1 = \{ u = 1 \}, b_c, b_0 = \{ \zeta = 1 \}$ for $R$.

### 3.2. Decomposition $R = f \circ Q$ and structure of $f$ on the cylinder.

To understand further the geometric structure (of the first iterate) of the renormalization $R$, it is convenient to decompose it as $f \circ Q$, where $Q(z, t) = (z^2, t^2)$ and

\begin{equation}
f(z, t) = \left( \frac{z + t}{z^{-1} + t}, \frac{\cos \phi + 1}{\cos \phi + s} \right), \quad s = \frac{1}{2} (t + t^{-1}).
\end{equation}

As a reflection of the basic symmetry of the Ising model, $f$ commutes with the involution $\sigma : (\phi, t) \mapsto (-\phi, t)$.

The cylinder $C$ is invariant under both $Q$ and $f$. However, we should be careful: $f$ is not well defined on the whole cylinder; it has a point of indeterminacy $\alpha = (\pi, 1) \in T \cap I_x$ which decisively influences the dynamics. When we approach $\alpha$ from

\textsuperscript{12}We hope it will be clear from the context whether the term “critical” is used in the physical or dynamical sense.
inside the cylinder at angle $\omega \in [-\pi/2, \pi/2]$ with the leaf $I_\pi$, the map $f$ converges to the point

\[(\phi, t) = (2\omega, \sin^2 \omega) := G(\omega) \in \mathbb{C}\]

(see [BZ3, p. 419] and also calculations in Appendix A.2). Thus, the point $\alpha$ blows up to the blow-up locus

\[G = \{ t = \sin^2 \phi/2 \equiv 1 - \cos \phi \} \cap \mathbb{C} \]

Note that $G$ touches the top $T$ at $\alpha$ itself, and touches the bottom $B$ at $\beta_0$ (see Figures 3.1 and 3.2). It divides the cylinder into two pieces: $C_-$ (below $\Gamma$) and $C_+$ (above it).

The interval $I_\pi$ (that ends at the point of indeterminacy $\alpha$) is critical: it collapses under $f$ to the fixed point $\beta_0$.

In the angular coordinate, we have:

\[Df = \frac{2}{\eta^2} \begin{pmatrix} \eta & 0 \\ 0 & 1 - t \end{pmatrix} \cdot \begin{pmatrix} 1 + t \cos \phi & -\sin \phi \\ -t(1 - t) \sin \phi & (1 + t)(1 + \cos \phi) \end{pmatrix} \]

where $\eta = 1 + 2t \cos \phi + t^2 \in [0, 4]$. It follows that

\[\text{Jac } f = \frac{4(1 - t)(1 + \cos \phi)}{\eta^2} \geq 0,\]

and $\text{Jac } f = 0$ only on the critical interval $I_\pi$. Thus, $f$ is an orientation preserving local diffeomorphism on $C \setminus I_\pi$.

Note that $f|B : z \mapsto z^2$ while $f|T = \text{id}$. This drop in the degree is caused by the point of indeterminacy in the following way. Let us consider the zero level Lee-Yang locus $S = \{ Z = 0 \}$, where $Z$ is the partition function (2.17):

\[S = \{ z^2 + 2tz + 1 = 0 \} = \{ t = -\cos \phi : \phi \in [\pi/2, 3\pi/2] \} \]

It has two branches over $I$ (symmetric with respect to $I_\pi$) each of which is mapped diffeomorphically onto $I_\pi$ (see Figure 3.1).

The curve $S$ divides $C$ into two domains: $\Lambda^s$ (containing $I_\pi \setminus \{ \alpha \}$) and $\Lambda^r$ (containing $I_\pi$). The domain $\Lambda^s \setminus I_\pi$ is composed of two topological triangles mapped diffeomorphically onto the corresponding triangles of $C_- \setminus I_\pi$, namely, the right-hand side triangle of $\Lambda^s \setminus I_\pi$ is mapped onto the left-hand side triangle of $C_- \setminus I_\pi$, see Figure 3.2. On the other hand, $\Lambda^r$ is mapped diffeomorphically onto the whole $C \setminus I_\pi$. Accordingly, we have two diffeomorphic branches of the

\[\text{The map is quite peculiar on the boundary of $\Lambda^r \setminus I_\pi$ as it blows up $\alpha$ to the $G$-boundary of $(C_- \setminus I_\pi)$ while collapses $I_\pi$ to $\beta_0$.} \]
inverse map, the “singular” branch \( f^{-1}_s : C_- \setminus \mathcal{I}_\pi \to \Lambda^s \) and the “regular” one, \( f^{-1}_r : C \setminus \mathcal{I}_\pi \to \Lambda^r \).

In particular, we conclude that the map \( f \) has degree 2 over \( \text{int} \; C_- \) and degree 1 over \( \text{int} \; C_+ \). So, \( f \) is not a proper map.

A path \( \gamma : [0, 1] \to C \) is called proper if it connects the bottom of the cylinder to its top without passing through \( \partial C \) in between.\(^{14}\) A crucial property of the cylinder dynamics is that \( f^{-1} \) acts properly on proper paths:

**Lemma 3.2.** If \( \gamma : [0, 1] \to C \) is a proper path then the full preimage \( f^{-1} \gamma \) contains two proper paths, \( \delta_1 \) and \( \delta_2 \). These two paths can meet only at \( \alpha \). Moreover, if \( \gamma \) crosses \( \mathcal{G} \) only once, then \( f^{-1} \gamma = \delta_1 \cup \delta_2 := \delta_r \cup \delta_s \), where \( \delta_r = f^{-1}_r \gamma \) is the “regular” lift of \( \gamma \) while \( \delta_s = f^{-1}_s \gamma \) is the “singular” lift ending at \( \alpha \).\(^{15}\)

**Proof.** Since the endpoints of \( \gamma \) belong to different components of \( \partial C \), we can orient it so that \( \gamma(0) \in \mathcal{B} \). This initial point has two preimages on \( B \); let \( p \) be either of them. We will show that there is a proper path \( \delta \subset f^{-1} \gamma \) that begins at \( p \).

Let \( \alpha_0 = (\pi, 0) \in \mathcal{B} \) stand for the bottom point of the critical interval \( \mathcal{I}_\pi \) (which collapses to \( \beta_0 \)). If \( p = \alpha_0 \) then \( \gamma(0) = \beta_0 \) and the interval \( \mathcal{I}_\pi \) is a desired path \( \delta \).\(^{16}\)

So, assume \( p \neq \alpha_0 \). Then \( f : C \to C \) is a local diffeomorphism near \( a \), so there is a local lift \( \delta \) of \( \gamma \) that begins at \( a \). Continuing lifting it as far as possible, we obtain a lift \( \delta(\lambda), 0 \leq \lambda < \lambda_\alpha \in (0, 1], \) that cannot be extended further.

---

\(^{14}\)An open path \( \gamma_1 : (0, 1) \to \text{int} \; C_1 \) or a half-open path \( \gamma_1 : [0, 1) \to C_1 \) that extends to a proper path \( \gamma : [0, 1] \to C_1 \) will also be called “proper”.

\(^{15}\)In case \( \gamma(1) = \alpha \), both lifts end at \( \alpha \).

\(^{16}\)If an initial piece of \( \gamma \) lies in \( C_- \) then there is a lift \( \delta' \) of \( \gamma \) that begins at \( \alpha_0 \). This possible extra lift is disregarded in our discussion.
What can go wrong at $\lambda_*$? If $x := \gamma(\lambda_*) \notin T \cup \mathcal{G}$ then $x$ would have a disk neighborhood $U \subset \text{int} \, \mathcal{C}$ such that $f : f^{-1}(U) \to U$ were a covering map (of degree 1 or 2), and the lift would admit a further extension. So, $x \in T \cup \mathcal{G}$.

If $x \in T \setminus \{ \alpha \}$ then $\lambda_* = 1$ and $x$ has a relative half-disk neighborhood $U \subset \mathcal{C}$ such that $f^{-1}(U)$ is a half-disk neighborhood of $f^{-1}x = x$ mapped homeomorphically onto $U$. In this case we let $\delta(1) = x$ and obtain the desired lift.

If $x \in \mathcal{G} \setminus \{ \alpha \}$ then $x$ has a neighborhood $U \subset \text{int} \, \mathcal{C}$ such that $f^{-1}U = U^r \sqcup U^s$ where $U^r = f^{-1}_r(U)$ is a disk homeomorphically mapped onto $U$, while $U^s = f^{-1}_s(U \cap \mathcal{C}_-)$ is a “wedge centered at $\alpha$” homeomorphically mapped onto $U \cap \mathcal{C}_-$. Then for all $\lambda$ near $\lambda_*,$

$$f^{-1}(\gamma(\lambda)) \subset U^r \text{ or } f^{-1}(\gamma(\lambda)) \subset U^s.$$

But in the latter case, $\delta(\lambda)$ can be extended beyond $\lambda_*$ contrary to our assumption.

In the latter case, $\delta(\lambda)$ is forced to converge (as $\lambda \to \lambda_*$) to the center $\alpha$ of the wedge $U^s$. This gives us the desired proper path terminating at $\alpha$.

Finally, if $x = \alpha$ then $\lambda_* = 1$ and $\alpha$ can be the only accumulation point for $\delta(\lambda)$ as $\lambda \to 1$ (for, if $y \in \mathcal{C} \setminus \{ \alpha \}$ is another accumulation point then $\gamma(\lambda)$ would accumulate on $f(y) \neq \alpha$ as $\lambda \to 1$). Thus, $\delta(\lambda) \to \alpha$ as $\lambda \to 1$, and we obtain a proper path again.

Remark that if $\delta \neq \mathcal{I}_\pi$ then the path $\delta(\lambda)$ cannot meet $\mathcal{I}_\pi \setminus \{ \alpha \}$. Indeed, under this assumption, $\beta_0 \notin \gamma$, while $\mathcal{I}_\pi$ collapses to $\beta_0$. So, we have constructed two proper paths, $\delta_1$ and $\delta_2$. They cannot meet at any point of $\mathcal{C} \setminus \mathcal{I}_\pi$ since $f$ is a local homeomorphism over there. By the above remark, they cannot meet at any point of $\mathcal{I}_\pi \setminus \{ \alpha \}$ either. Hence $\alpha$ is their only possible meeting point.

Assume now that $\gamma$ crosses $\mathcal{G}$ only once, and let $\gamma(\lambda_* \in \mathcal{G}$ be this intersection point. Assume first that $\gamma(0) \neq \beta_0$. Then by the previous argument, the arc $\gamma(\lambda)$, $0 \leq \lambda < \lambda_*$, has two lifts $\delta_r(\lambda)$ and $\delta_s(\lambda)$ as in (3.9). Then $\delta_r(\lambda)$, $0 \leq \lambda \leq \lambda_*$, is a proper path terminating at $\alpha$ (the singular lift of $\gamma$), while $\delta_r(\lambda)$ extends further to a proper path parameterized by the full interval $[0, 1]$ (the regular lift of $\gamma$).

Thus, for $\lambda < \lambda_*$, both preimages of $\gamma(\lambda)$ are captured by the above lifts $\delta_r(\lambda)$ and $\delta_s(\lambda)$, while for $\lambda > \lambda_*$, the only preimage of $\gamma(\lambda)$ is $\delta_r(\lambda)$. We conclude that $f^{-1}(\gamma) = \delta_r \cup \delta_s$.

Finally, if $\gamma(0) = \beta_0$ then $\gamma(\lambda) \in \mathcal{C}^+$ for $\lambda > 0$, so such $\gamma(\lambda)$ has only one preimage. This preimage is captured by the lift $\delta_r$ that begins at $\beta_0$. It follows that

$$f^{-1}(\gamma) = \delta_r \cup f^{-1}(\beta_0) = \delta_r \cup \mathcal{I}_\pi := \delta_r \cup \delta_s.$$

Figure 3.2 shows $\mathcal{C}$ in $(\phi, t)$ coordinates, a proper path $\gamma$ that crosses $\mathcal{G}$ in only one point, and the regular and singular lifts $\delta_r$ and $\delta_s$ of $\gamma$ under $f$.

If $\eta$ is not a full proper path, but merely a proper path in $\mathcal{C}_-$ (connecting $B$ to $\mathcal{G}$ without passing through $\partial \mathcal{C}_-$ in between) we will also call the lift of $\eta$ under $f_s^{-1}$ the “singular lift” of $\eta$.

$^{17}$Note that the curve $\gamma(\lambda)$ can cross $\mathcal{G}$ infinitely many times at $\lambda \to \lambda_*$. If this happens then $\delta(\lambda) = f^{-1}_s(\gamma(\lambda))$ for $\lambda$ near $\lambda_*$. 
3.3. Structure of \( \mathcal{R} \) on the cylinder. The above properties of \( f \) immediately translate into the following properties of the renormalization operator \( \mathcal{R} \):

(P1) **Symmetries:** As we have already mentioned in §2.5, the Basic Symmetry of the Ising model implies that \( \mathcal{R} \) commutes with the involution \( \iota : (z,t) \mapsto (z^{-1}, t) \). On the other hand, since \( \mathcal{R} = f \circ Q \), we have: \( \mathcal{R} \circ \rho = \mathcal{R} \), where \( \rho : (z,t) \mapsto (-z,t) \). It follows that the basins of the top and the bottom of \( \mathcal{C} \) are invariant under the Klein group \( (\mathbb{Z}/2\mathbb{Z}) \times (\mathbb{Z}/2\mathbb{Z}) \) comprising \( \iota \), \( \rho \) and \( \iota \circ \rho \). These symmetries are clearly visible on Figure 1.2 as it is \( 18\pi \)-periodic and is invariant under reflections in the axes \( \phi = 0, \pi \), \( \phi = \pm \pi/2 \).

(P2) \( \mathcal{R} \) has two points of indeterminacy, \( \alpha_{\pm} = (\pm \pi/2, 1) \in \mathcal{T} \). Each of them blows up onto the singular curve \( \mathcal{G} \). (See Appendix A.2 for detailed formulæ.)

(P3) Formula (3.7) implies that the critical locus of \( \mathcal{R}|\mathcal{C} \) comprises the bottom \( \mathcal{B} \), the top \( \mathcal{T} \), and two vertical intervals, \( \mathcal{I}_{\pm \pi/2} \), terminating at the points of indeterminacy. These intervals collapse under \( \mathcal{R} \) to the fixed point \( \beta_1 \in \mathcal{B} \). \( \mathcal{R} \) is an orientation preserving local diffeomorphism on the complement of the critical set, \( \mathcal{C} \setminus (\mathcal{I}_{\pm \pi/2} \cup \mathcal{T} \cup \mathcal{B}) \).

(P4) \( \mathcal{R} \) is postcritically finite in the following sense: \( \mathcal{C} \setminus (\mathcal{I}_{\pm \pi/2} \cup \mathcal{T} \cup \mathcal{B}) \) is backward invariant, and \( \mathcal{R} \) is a local diffeomorphism on this set. (Note: while postcritically finite maps typically have rather simple dynamics, \( \mathcal{R} \) is not postsingularly finite, since images of the curve \( \mathcal{G} \) are not eventually periodic, leading to dynamical complexity of \( \mathcal{R} \).)

(P5) \( \mathcal{R}|\mathcal{B} : z \mapsto z^4 \), while \( \mathcal{R}|\mathcal{T} : z \mapsto z^2 \). Moreover, the bottom circle is uniformly superattracting, namely, letting \( \mathcal{R}(z,t) = (z',t') \), we have: \( t' = O(t^2) \) for \( t \) near 0. The top circle is non-uniformly superattracting, namely, near the top we have

\[
\tau' = O\left(\frac{\tau^2}{\cos^2 \phi}\right) = O\left(\frac{\tau^2}{\epsilon^2}\right), \quad \tau = 1 - t, \quad \epsilon = \pi/2 - \phi \mod \pi \mathbb{Z},
\]

so that, the superattraction rate explodes near the points of indeterminacy. See Figure 1.2 for a computer image of the basins of attraction for \( \mathcal{B} \) and \( \mathcal{T} \).

(P6) The preimage \( Q^{-1}(\mathcal{S}) \) comprises two curves \( S_{\pm} \) that are tangent to \( \mathcal{T} \) at the indeterminacy points \( \alpha_{\pm} \) and are symmetric with respect to \( \mathcal{I}_{\pm} \) respectively. The domains below them are called the (primary) central tongues \( \Lambda_{\pm} \), see Figure 3.3. The vertical intervals \( \mathcal{I}_{\pm \pi/2} \) cut the corresponding tongues \( \Lambda_{\pm} \) into two topological triangles. Each of these (open) triangles is mapped diffeomorphically by \( \mathcal{R} \) onto the appropriate triangle of \( \mathcal{C}_- \setminus \mathcal{I}_{\pi} \). The inverse diffeomorphisms are called singular branches of \( \mathcal{R}^{-1} \).

(P7) The complement \( \Pi := \mathcal{C} \setminus \Lambda_+ \cup \Lambda_- \) consists of two domains each of which is mapped diffeomorphically onto the cut rectangle \( \mathcal{C} \setminus \mathcal{I}_{\pi} \). The inverse diffeomorphisms are called regular branches of \( \mathcal{R}^{-1} \).

(P8) \( \mathcal{R} \) has degree 4 over \( \mathcal{C}_- \) and it has degree 2 over \( \mathcal{C}_+ \).

(P9) By Lemma 3.2, every proper path \( \gamma \) in \( \mathcal{C} \) has at least 4 proper lifts \( \delta_i \). These lifts can meet only at the indeterminacy points \( \alpha_{\pm} \). If \( \gamma \) crosses \( \mathcal{G} \) at

\[18\text{or rather, its } 2\pi\text{-periodic unfolding}\]
a single point, then $R^{-1}\gamma = \cup \delta_i$. Two of these lifts (contained in $\Lambda_{\pm}$) are “singular”: they terminate at the points $\alpha_{\pm}$; the other two are “regular”.

(P10) $R$ acts with degree 4 on closed curves: If $\gamma$ is any closed curve on $C$ wrapping once around $C$, then $R(\gamma)$ is a closed curve wrapping four times around $C$.

3.4. Structure of $R$ on the Möbius band. Because of the conjugacy $\Psi : C_0 \to C_0$ from Proposition 3.1, the structural properties (P1-P10) for $R : C \to C$ discussed in §3.3 have immediate analogs for $R : C \to C_0$. Particularly important is

(P9') Every proper path $\gamma$ in $C_0$ lifts under $R$ to at least 4 proper paths in $C_0$. If $\gamma$ crosses $G$ at a single point, then $R^{-1}\gamma = \cup \delta_i$.

(Here a path in $C_0$ is called proper if it goes from $T$ to $\infty$).

Also, we have:

- The principal LY locus $S$ in $C$ (see (3.8)) is turned into the vertical line $S = \{\Re u = -1\}$ in $C_p$. (This is seen directly from the formula (2.17) for the partition function). We will refer to $S$ as the principal LY locus in the affine coordinates.
- The indeterminacy points $\alpha_{\pm} \in T$ for $R$ are turned into indeterminacy point $\pm i \in T$ for $R$.
- The blow-up locus $G$ (3.5) is turned into the parabola

$$G = \{u : |u| = \Re u + 2\} = \{x + iy : x = \frac{1}{4}y^2 - 1\}$$

(use $u^{-1} = te^{i\phi}$). See Figure 6.4.

Let us rotate the LY locus $S$ around the circle $T$. We obtain a family of lines $S_\phi = e^{i\phi}S$ tangent to $T$ at $e^{i\phi}$. Let $S_\phi^C = \{e^{-i\phi}U + 2V + e^{i\phi}W = 0\}$ be the corresponding complex line in $\mathbb{CP}^2$. By Corollary 4.5, the pullback $R^*(S_\phi^C)$ is a complex algebraic curve of degree 4. By Bezout’s Theorem, it intersects the conic $L_1 = \{uw = 1\}$ (which is the complexification of the circle $T$) at 8 points counted with multiplicity.
Lemma 3.3. (i) If $\phi \neq \pi$ (i.e., $S_\phi \neq S$), then the conic $L_1$ intersects the pullback $R^*(S_\phi^c)$ transversally at four transverse double points ($\pm e^{\psi/2}$ and the indeterminacy points $\pm i$). So, each intersection has multiplicity 2.

(ii) If $\phi = \pi$ (i.e., $S_\phi = S$), then $L_1$ intersects $R^*(S_\phi^c)$ tangentially at two first order tangential double points (the indeterminacy points $\pm i$). So, each intersection has multiplicity 4.

Proof. (i) By Lemma D.3, the map $R$ is a Whitney fold at $\pm e^{i\psi/2}$. By Lemma D.4, the germ of $R^*(S_\phi^c)$ at $\pm e^{i\psi/2}$ is a transverse double point transversely intersected by the critical locus $L_1$.

To understand the germ of $R^*(S_\phi^c)$ at an indeterminacy point $a \in \{\pm i\}$, let us blow it up and lift $R$ to a map $\tilde{R} : \mathbb{C}P^2 \to \mathbb{C}P^2$, see Appendix A.2. The blow-up locus $G = \tilde{R}(E_{exc})$ intersects $S_\psi$ transversely at two points which are regular values for $\tilde{R}$ (Lemma D.1.1). Hence the curve $\tilde{R}^*(S_\psi^c)$ intersects the exceptional divisor $E_{exc}$ transversally at two points. Projecting the corresponding germs to $\mathbb{C}P^2$, we obtain two branches of $R^*(S_\phi^c)$ at $a$.

(ii) By Lemma D.3, the blow-up map $\tilde{R} : \tilde{L}_1 \to L_1$ is a Whitney fold at the intersection point $\tilde{a} = \tilde{L}_1 \cap E_{exc}$. Hence the germ of $\tilde{R}^*(S_\psi)$ has a transverse double point at $\tilde{a}$ and intersects $E_{exc}$ generically. Its projection to $\mathbb{C}P^2$ is a pair of regular curves tangent to $L_1$ at $a$ (see Lemma D.5). □

Remark 3.2. The above lemma is reflected in the geometry of the initial LY loci illustrated on Figure 1.3. The locus $S_1 = \mathcal{R}^{-1}S_0$ looks like two tangent parabolas near the indeterminacy points $\alpha_\pm$ (part (ii) of the lemma). The next locus, $S_2 = \mathcal{R}^{-1}S_1$, comprises 32 branches meeting transversely at the top, as part (i) asserts.

4. Structure of the RG transformation II: Global properties in $\mathbb{C}P^2$

The Lee-Yang Theorem places special emphasis of the dynamics of $\mathcal{R}$ on the cylinder $C$. However, it is instructive to understand the global dynamics of $\mathcal{R}$ on the projective space $\mathbb{C}P^2$, which has important consequences for the dynamics of $\mathcal{R}|C$. In this section we will describe basic global properties of $\mathcal{R}$, along with those of $\tilde{R} : \mathbb{C}P^2 \to \mathbb{C}P^2$.

4.1. Semiconjugacy $\Psi$. The mapping $\Psi$ given by (2.21) is a degree two rational map $\mathbb{C}P^2 \to \mathbb{C}P^2$. In homogeneous coordinates $[Z : T : Y]$ in the domain (with $z = Z/Y$, $t = T/Y$) and $[U : V : W]$ in the image (with $u = U/V$, $w = W/V$), it assumes the form

$$U = Y^2, \quad V = ZT, \quad W = Z^2.$$ 

A generic point $[U : V : W]$ has two preimages under $\Psi$. The critical locus of $\Psi$ is the union of the vertical axis $\{Z = 0\}$ and the line at infinity $\{Y = 0\}$. Under $\Psi$, the former collapses to an $R$-fixed point $e = [1 : 0 : 0]$, while the latter maps onto the vertical axis $\{U = 0\}$. Since $e$ does not lie on this axis, the intersection $\gamma = [0 : 1 : 0]$ of the two critical lines must be an indeterminacy point for $\Psi$ (and in fact, this is the only one).

This collapsing line $\{Z = 0\}$ and the associated indeterminacy point $\gamma$ created by the change of variable $\Psi$ is what makes the physical coordinates $(z, t)$ less suitable for describing the global structure of the renormalization.
4.2. Indeterminacy points for \( R \) and \( R \). In homogeneous coordinates on \( \mathbb{CP}^2 \), the map \( R \) has the form:
\[
(4.1) \quad R : [U : V : W] \mapsto [(U^2 + V^2)^2 : V^2(U + W)^2 : (V^2 + W^2)^2)]
\]
which is just (2.18) with \((U,V,W)\) interpreted as the homogeneous coordinates. We find two points of indeterminacy: \( a_+ := [i : 1 : -i] \) and \( a_- := [-i : 1 : i] \). They lie on the M"obius band \( C \) and correspond under \( \Psi \) to the indeterminate points \( \alpha_\pm \in \mathcal{C} \) that we discussed in \S 3.1.

If we now write \( R \) in homogeneous coordinates we obtain
\[
(4.2) \quad R : [Z : T : Y] \mapsto [Z^2(Z^2 + T^2)^2 : T^2(Z^2 + Y^2)^2 : (Z^2 + T^2)(T^2Z^2 + Y^4)].
\]

We find the indeterminate points \( \alpha_\pm = (\pm i, 1) \in \mathcal{C} \), two symmetric points \((\pm i, -1)\), and two additional points of indeterminacy, \( 0 = (0, 0) \) and \( \gamma = [0 : 1 : 0] \) (here all the points except the last one are written in the physical coordinates \( z = Z/Y, t = T/Y \)). In this way, when we turn \( R \) into \( R \) by the change of variable \( \Psi \) we create two accidental points of indeterminacy, \( 0 \) and \( \gamma \), which makes the global properties of the map more awkward.

One can resolve all the indeterminacies of \( R \) using suitable blow-ups. We will only need resolutions of \( \alpha_\pm \), which are described in Appendix A.2.

4.3. Superattracting fixed points and their separatrices.

4.3.1. Description in terms of \( R \) (4.1). We will often refer to \( L_0 := \{ V = 0 \} \subset \mathbb{CP}^2 \) as the \textit{line at infinity}. It contains two symmetric fixed points, \( e = (1 : 0 : 0) \) and \( e' = (0 : 0 : 1) \). In local coordinates \( (\xi = W/U, \eta = V/U) \) near \( e \), the map \( R \) assumes form
\[
(4.3) \quad \xi' = \left( \frac{\xi^2 + \eta^2}{1 + \eta^2} \right)^2 \sim (\xi^2 + \eta^2)^2, \quad \eta' = \eta^2 \left( \frac{1 + \xi}{1 + \eta^2} \right)^2 \sim \eta^2,
\]
so \( |Rx| \leq 2|x|^2 \) for small \( x = (\xi, \eta) \). This shows that \( e \) is superattracting:
\[
|R^n x| \leq 2^n |x|^n.
\]

By symmetry, \( e' \) is superattracting as well. Let \( W^w(e) \) and \( W^s(e') \) stand for the attracting basins of these points.

Moreover, the line at infinity \( L_0 = \{ \eta = 0 \} \) is \( R \)-invariant, and the restriction \( R|L_0 \) is the power map \( \xi \mapsto \xi^4 \). Thus, points in the disk \( \{ |\xi| < 1 \} \) in \( L_0 \) are attracted to \( e \), points in the disk \( \{ |\xi| > 1 \} \) are attracted to \( e' \), and these two basins are separated by the unit circle \( B \). We will also call \( L_0 \) the \textit{fast separatrix} of \( e \) and \( e' \).

Let us also consider the conic
\[
(4.4) \quad L_1 = \{ \xi = \eta^2 \} = \{ V^2 = UW \}
\]
passing through points \( e \) and \( e' \). It is an embedded \( \mathbb{CP}^1 \) that can be uniformized by coordinate \( w = W/V = \xi/\eta \). Formulas (4.3) show that \( L_1 \) is \( R \)-invariant, and the restriction \( R|L_1 \) is the quadratic map \( w \mapsto w^2 \). Thus, points in the disk \( \{ |w| < 1 \} \) in \( L_1 \) are attracted to \( e \), points in the disk \( \{ |w| > 1 \} \) are attracted to \( e' \), and these two basins are separated by the unit circle \( T \). We will call \( L_0 \) the \textit{slow separatrix} of \( e \) and \( e' \).
If a point $x$ near $e$ (resp. $e'$) does not belong to the fast separatrix $L_0$, then its orbit is “pulled” towards the slow separatrix $L_1$ at rate $\rho^n$, with some $\rho < 1$, and converges to $e$ (resp. $e'$) along $L_1$ at rate $r^n$, with some $r < 1$.

The second formula of (4.3) also shows that the strong separatrix $L_0$ is transversally superattracting: all nearby points are pulled towards $L_0$ uniformly at rate $r^n$ (see also the proof of Lemma D.3). It follows that these points either converge to one of the fixed points, $e$ or $e'$, or converge to the circle $B$.

Given a neighborhood $\Omega$ of $B$, let
\begin{equation}
W^s_{c,loc}(B) = \{ x \in \mathbb{CP}^2 : R^n x \in \Omega \ (n \in \mathbb{N}) \text{ and } \mathbb{R}^n x \rightarrow B \ \text{as} \ n \rightarrow \infty \}
\end{equation}
(where $\Omega$ is implicit in the notation, and an assertion involving $W^s_{c,loc}$ means that it holds for arbitrary small suitable neighborhoods of $B$).

We conclude:

**Lemma 4.1.** $\mathcal{W}^s(e) \cup \mathcal{W}^s(e') \cup W^s_{c,loc}(B)$ fills in some neighborhood of $L_0$.

As the weak separatrix $L_1$ is concerned, formula (D.1) from the proof of Lemma D.3 shows that it is transversally superattracting away from the indeterminacy points $a_{\pm}$. On the other hand, the latter act as strong repellers. We will see in §10 that this competition makes $T$ a non-uniformly hyperbolic attractor.

### 4.3.2. Description in terms of $\mathcal{R}$.

In the physical coordinates, the superattracting fixed points become $\eta = (0, 1)$ and $\eta' = [1 : 0 : 0]$. The pullback of the line at infinity $L_0$ under the semi-conjugacy $\Psi$ comprises two lines, $L_0 = \{ t = 0 \}$ and $\{ z = 0 \}$, where the latter is the blow-up of the fixed point $e$ under $\Psi^{-1}$. These two lines form the fast separatrix of the fixed points (recall that the latter collapses to $\eta = (0, 1)$ under $\mathcal{R}$), which is an annoying artifact of the physical coordinates. A related nuisance is that $L_0$, unlike $L_0$, is not transversally superattracting any more. Namely, it is superattracting away from the origin $0$, but the latter blows up to the whole line $\{ z = 0 \}$. Still, we will sometimes refer to $L_0$ itself as the “fast separatrix”, as long as it does not lead to confusion.

The slow separatrix of the fixed points is the line $\{ t = 1 \}$. The restrictions of $\mathcal{R}$ to the separatrices $L_0$ and $L_1$ become the power maps $z \mapsto z^4$ and $z \mapsto z^2$ respectively. The invariant circles on these lines (separating the basins of the fixed points) become $\mathcal{B} = \mathbb{T} \times \{ 0 \}$ and $\mathcal{T} = \mathbb{T} \times \{ 1 \}$, which are the bottom and the top of the physical cylinder $\mathcal{C}$ that we discussed in §3.

Lemma 4.1 implies:

**Lemma 4.2.** $\mathcal{W}^s(\eta) \cup \mathcal{W}^s(\eta') \cup W^s_{c,loc}(B)$ fills in some neighborhood of $L_0 \setminus \{ 0 \}$.

### 4.4. Critical locus.

The critical locus of $\mathcal{R}$ is described in Appendix, §D. Besides the separatrices $L_0$ and $L_1$, it comprises the line $L_2$ that collapses to the low temperature fixed point $b_0$, and two symmetric pairs of lines, $L_3$ and $L_4$. The latter wander under the dynamics.

The critical locus is schematically depicted on Figure 4.1, while its image, the critical value locus, is depicted on Figure 4.2.

In terms of the physical coordinates, the critical locus comprises:
- $\Psi^{-1}L_0$: the fast separatrix $L_0 \cup \{ z = 0 \}$;
- $\Psi^{-1}L_1$: the slow separatrix $L_1$ and its companion $\{ t = -1 \}$ (mapped to $L_1$ under $\mathcal{R}$);
- $\Psi^{-1}L_2$: two collapsing lines, $z = \pm i$. 
Figure 4.1. Critical locus for \( R \) shown with the separatrix \( L_0 \) at infinity.

Figure 4.2. Critical values locus of \( R \).

- \( \Psi^{-1}L_3 \): two conics \( zt = \pm i \);
- \( \Psi^{-1}L_4 \): two lines \( z = \pm it \) (symmetric to the above conics).

4.5. **Topological degree.** The topological degree \( \text{deg}_{\text{top}}(f) \) of a rational mapping \( f : \mathbb{P}^k \to \mathbb{P}^k \) is the number of preimages under \( f \) of a generic point \( \zeta \in \mathbb{P}^k \).

**Proposition 4.3.** We have \( \text{deg}_{\text{top}}(R) = \text{deg}_{\text{top}}(\mathcal{R}) = 8 \).

**Proof.** This can be seen for \( R \) by taking, e.g., a point \( \zeta = (u, u) \in \mathbb{C}^2 \) far away, and hence close to the separatrix \( L_0 \). Such a point has 8 preimages under \( R \), since the transverse degree of \( R \) at \( L_0 \) is equal to 2, while \( \text{deg}(R|_{L_0}) = 4 \).

Similarly for \( \mathcal{R} \), consider a generic point \( \zeta \) sufficiently close to, but not on, the separatrix \( \mathcal{L}_0 \).

4.6. **Algebraic degrees and pullbacks of curves.** The reader can consult Appendix A.3 for needed background in elementary algebraic geometry.
4.6.1. Case of $R$. Since $R$ is given in homogeneous coordinates by relatively prime equations of degree 4, we have $\deg R = 4$.

The notion of algebraic stability is essential to understanding pullbacks of curves (considered as divisors) under iterates of rational mappings, see Appendix A.3.

**Proposition 4.4.** The mapping $R: \mathbb{CP}^2 \to \mathbb{CP}^2$ is algebraically stable.

**Proof.** The only collapsing curve is $L_2$, whose orbit lands on the low-temperature fixed point $b_0$. □

It follows that $\deg R^n = (\deg R)^n = 4^n$, and hence we have:

**Corollary 4.5.** If $D$ is an algebraic curve of degree $d$, then the pullback $(R^n)^* D$ is a divisor of degree $d \cdot 4^n$.

4.6.2. Case of $R$. Since $R$ is given in homogeneous coordinates by relatively prime equations of degree 6, we have $\deg R = 6$. In particular, for any algebraic curve $X$ we have $R^* X$ is a divisor of degree $6 \cdot \deg X$. The degrees of pullbacks under iterates of $R$ are less organized:

**Observation 4.6.** The mapping $R: \mathbb{CP}^2 \to \mathbb{CP}^2$ is not algebraically stable.

Indeed, $R$ maps the lines $Z = \pm iT$ to the point of indeterminacy $\gamma = (0 : 1 : 0)$ since the first and third coordinates of (4.2) contain the factor $(Z^2 + T^2)$. 

**Remark 4.1.** In this case, algebraic instability results in a drop of degree for the second iterate of $R$. We have $\deg (R^2) = 28 < 36 = (\deg R)^2$, since the common factor of $(Z^2 + T^2)^4$ appears in the expression for $R^2$, which must be canceled.

**Figure 4.3.** The LY cylinder $C$ situated between the strong separatrix $L_0$ and the weak separatrix $L_1$. The collapsing lines at $z = 0, \pm i$ are shown in grey and the indeterminate points $\alpha, 0, \gamma$ are depicted by stars. The superattracting fixed point $\eta' = (0, \infty)$ is “symbolically” shown at a finite location.
of degree 2. Besides

By (2.5), the partition function

\[ Z_n \]

\[ Z_n(2.19), \]

\[ z, t \]

so every point \( (z, t) \) under some iterate \( T_n \) top comprises at least 2 different intersections with the circle \( \{ |u| = t^{-1} \} = P_t \cap C \). Hence all the intersection points of \( (R^n)^*L \) with \( P_t \) are captured on the cylinder \( C \), and all of them are simple.

6. ALGEBRAIC CONE FIELD

In this section we will construct a horizontal invariant cone field on the cylinder. It appears as the tangent cone field to a pair of transverse algebraic foliations obtained by translating the principal Lee-Yang locus around the cylinder or the Möbius band. In the affine coordinates on the Möbius band, these foliations assume a particular simple linear form.

\[ 19 \text{ Equivalently, } b = a, c \in \mathbb{R} \setminus \{0\} \text{ or } |b| = |a|, c = 0. \]
6.1. Algebraic cone fields. Let us consider the Möbius band $C$ introduced in §3.1, 
\[ \text{int } C = \{(u, w) \in \mathbb{C}^2 : u = \overline{w} \text{ and } |u| > 1\} \approx \mathbb{C} \setminus \overline{D}. \]
Recall that $S_\psi$ stands for the line tangent to $T$ at $e^{i\psi}$. We define an algebraic horizontal cone field $K^{ah}(u)$ on int $C$ as follows. For any $u \in \mathbb{C} \setminus \overline{D}$, there are two tangents lines $S_{\psi_1}$ and $S_{\psi_2}$ passing through $u$. Then, $K^{ah}(u)$ is the open cone bounded by $S_{\psi_1}$ and $S_{\psi_2}$ that does not contain $T$ (see Figure 6.1).

This construction can be described in terms of the principal LY locus $S = \{\text{Re } u = -1\}$ on $C$ (see §3.4). The line $S$ is a concatenation of two rays, $S^+ = \{u \in S : \text{Im } u > 0\}$ and $S^- = \{u \in S : \text{Im } u < 0\}$, meeting at $-1 \in T$. Rotating these rays around the origin, we obtain two linear foliations $\Phi^\pm$ of int $C$ (comprised of the leaves $S_\theta^\pm = e^{i\theta}S^\pm$). The cone $K^{ah}(u)$ is bounded by (the tangent lines to) the leaves of these foliations passing through $u$.

Described in this way, the construction can be immediately transferred to the cylinder $C$. Rotating the principal LY locus $S$ around the cylinder, we obtain two transverse foliations of int $C$. Then the horizontal cone field is formed by the tangent cones $K^{ah}(\omega)$ bounded by the tangent lines to the two leaves meeting at $\omega$ (see Figure 6.2). Clearly $K^{ah}(\omega) = D\Psi^{-1}(K^{ah}(u))$, where $u = \Psi(\omega)$.

Remark 6.1. In fact, this cone field extends to the bottom $B$ of $C$, so it is well defined on the topless cylinder $C_1$. However, it degenerates to a line field at the top.

\[ ^{20}\text{Here a "cone" comprises two symmetric wedges. Also, more precisely one should think of } K^{ah}(u) \text{ as the tangent cone at } u. \]
A smooth path $\gamma(t)$ in $C$ is called \textit{horizontal} if it goes through the cones $K^{ah}(x)$, i.e. $\gamma'(t) \in K^{ah}(\gamma(t))$ whenever $\gamma(t) \in \text{int} C$. (The same definition applies to the cylinder $C$.)

**Lemma 6.1.** The blow-up locus $G$ (respectively $G$) is horizontal.

**Proof.** See Figure 6.3. \hfill $\Box$

Let us now define the \textit{vertical cones} as the complements to the horizontal ones, $K^{av}(u) = T_u C \setminus K^{ah}(u)$. A smooth path $\gamma(s)$ is called \textit{vertical} if it goes through the vertical cones, i.e., $\gamma'(s) \in K^{av}(x)$. (The same definitions apply to the cylinder $C$.) We call a path \textit{strictly vertical} if it goes through the $\text{int} K^{av}(u)$.

**Lemma 6.2.** If $\gamma$ is a proper vertical path in $C$, then $R^{-1}\gamma$ comprises four proper paths (and similarly, for proper paths in $C$).

**Proof.** Obviously, vertical paths are transverse to horizontal ones – so, by Lemma 6.1, they are transverse to the blow-up locus $G$. Combined with Property (P9’), this yields the assertion. \hfill $\Box$

Given a cone $K$ in a linear space $E$, let $PK \subset PE$ stand for its projectivization. Let us say that a cone field $K(u)$ is \textit{strictly forward invariant} if

$DR(PK(u)) \Subset \text{int} PK(Ru)$.

**Proposition 6.3.** The horizontal cone fields $K^{ah}(u)$ and $K^{ah}(u)$ are strictly forward invariant under the corresponding dynamics, $R$ and $R$.

**Proof.** Equivalently, the vertical cone field $K^{av}(u)$ is strictly backward invariant. Since the cones are tangent to the pair of foliations $\Phi^\pm$, this is equivalent to the property that the pullbacks $R^{-1}(S^\pm_{\psi})$ of the $\Phi^\pm$-leaves are strictly vertical.

By Lemma 6.2, each pullback $R^{-1}(S^\pm_{\psi})$ comprises four disjoint proper paths in $C$. As the line $S_{\psi}$ is the concatenation of two rays $S^\pm_{\psi}$, the pullback $R^{-1}(S_{\psi})$ comprises eight disjoint proper paths $\gamma_i = \gamma_{i,\psi}$ in $\text{int} C$.

To prove the desired, it suffices to show that for any angles $\psi$ and $\theta$, each path $\gamma_{i,\psi}$ has at most one intersection point with any line $S_{\theta}$, and the intersection is transverse. In so, $\gamma_i$ could not cross $S_{\theta}$ through the horizontal cone $K^{ah}(u)$, for it would be disjoint from the whole closed vertical cone $\text{cl} K^{av}(u)$ (viewed as a subset of $C$). But the latter contains $T$, so $\gamma_i$ would fail to land on $T$ (see Figure 6.4).
Let \( S^c_\psi \) be the complexification of \( S_\psi \). Since \( R^*(S^c_\psi) \) is a complex algebraic curve of degree 4 (by Corollary 4.5), its slice by the complex line \( S^c_\theta \) consists of 4 points counted with multiplicity. We will show that the intersection points that lie in \( \text{int} \, C \) are transverse and belong to distinct radial components of \( R^{-1}(S_\psi) \). Let us consider several cases.

**Case 1 (generic).** Let \( \theta \neq \psi/2, \pi/2 \mod \pi \). Then \( S_\theta \) does not meet \( R^{-1}(S_\psi) \) on \( T \). Since \( R \) is even, both pullbacks \( R^{-1}(S^\pm_\psi) \) are symmetric with respect to the origin. Hence the rays comprising \( R^{-1}(S^\pm_\psi) \) come in symmetric pairs \( \gamma_i, \gamma'_i \), \( i = 1, \ldots, 4 \). Then one ray in each pair (say \( \gamma_i \)) near infinity is separated by \( S_\theta \) from \( T \). Since \( \gamma_i \) lands on \( T \), it must intersect \( S_\theta \). Since the \( \gamma_i \) are pairwise disjoint, this gives us 4 distinct intersection points of \( R^{-1}(S_\psi) \) with \( S_\theta \), and thus we have accounted for all of them. Thus, each \( \gamma_i \) intersects \( S_\theta \) exactly once and the intersection is transverse (while the \( \gamma'_i \) are disjoint from \( S_\theta \)).

**Case 2.** Let \( \theta = \psi/2 \) or \( \pi/2 \mod \pi \), but \( \psi \neq \pi \mod 2\pi \). By Lemma 3.3 (i), the algebraic curve \( R^*(S^c_\psi) \) has a double point at \( e^{i\theta} \), and \( S_\theta \) intersects it non-tangentially with multiplicity 2. It must intersect two other branches \( \gamma_i \) in \( \text{int} \, C \), and thus we have accounted for all four intersection points. The conclusion follows.

**Case 3.** Finally, let \( \theta = \psi/2 = \pi/2 \mod \pi \) (this is the most degenerate case, but it occurs exactly when \( S_\psi = S \) is the principal LY locus, see Figure 1.3). In this case, all four branches \( \gamma_i \) meet at the indeterminacy points \( e^{i\theta} \), and \( S_\theta \) intersects \( R^*(S^c_\psi) \) at this point with multiplicity 4 (as described Lemma 3.3 (ii)). It accounts for all intersection points, so no intersections occur in \( \text{int} \, C \).

**Remark 6.2.** Eric Bedford has informed us that a similar algebraic method for constructing an invariant cone field (for certain birational maps) had been earlier used in [BD, §5].

Corollary 6.2 and Proposition 6.3 imply:

**Corollary 6.4.** If \( \gamma \) is a proper vertical path in \( C \), then \( R^{-1}\gamma \) comprises four proper strictly vertical paths (and similarly, in \( C \)).

6.2. **Modified algebraic cone field.** The algebraic cone field we have just constructed has a disadvantage that it degenerates near the top. We will now modify...
it near the top so that it will become non-degenerate everywhere away from the indeterminacy points $\alpha_{\pm}$.

Given a small threshold $\bar{\tau} > 0$, let us consider the following annular neighborhood of the top:

\begin{equation}
V \equiv V_{\bar{\tau}} = \{ x \in C : \tau \leq \bar{\tau} \}.
\end{equation}

Given $\eta > 0$, let us consider two parabolas $Y_\eta^\pm = \{ \tau = \eta \epsilon^2 \}$ centered at the indeterminacy points $\alpha_{\pm}$.

Consider two parabolic regions $P_\pm^\eta$ below the curves $Y_\eta^\pm$ (see Figure 6.5), and let

\begin{equation}
V' \equiv V_{\bar{\tau}, \eta} = V_{\bar{\tau}} \setminus (P_\eta^+ \cup P_\eta^-).
\end{equation}

For a small threshold $\bar{\epsilon} > 0$, let us consider the following regions in $V$:

\begin{equation}
U \equiv U_{\bar{\epsilon}} = \{ x \in C : |\epsilon(x)| < \bar{\epsilon} \} \quad \text{and} \quad U' = \{ x \in V' : |\epsilon(x)| < \bar{\epsilon} \}.
\end{equation}

For the remainder of the construction, we let $\bar{\tau} = \eta \bar{\epsilon}^2$ so that the regions $U$ and $U'$ meet the parabolas $Y_\eta^\pm$ at their bottom, see Figure 6.5. To be definitive, we fix $\eta = 1/18$, so the only free parameter left in our disposal is $\bar{\epsilon}$.

Note that for $x \in Y_\eta^\pm$, the slope of the lines that bound the algebraic cone $K^a(x)$ is equal (in absolute value) to

\begin{equation}
s^a(x) = \sqrt{\tau(2-\tau)} \sim \sqrt{2\tau} = |\epsilon|/3, \quad \text{and} \quad s^a(x) \geq |\epsilon|/3.
\end{equation}

Lemma 6.5. For $\bar{\epsilon} > 0$ sufficiently small, we have:

(a) $R(U) \cap U = \emptyset$;

(b) $R^{-1}(U)$ is contained in a small neighborhood of the points $\phi = \pm \pi k/4, \tau = 0 \in T$ with $k = \pm1, \pm3$.

Proof. a) By blow-up formula (B.4), the image $R(U)$ is contained in a small neighborhood of the singular curve $G$, which is disjoint from $U$.

b) By (a), there are no points of $U$ in $R^{-1}U$. But in $C \setminus U$, the map $R$ is continuous, so $R^{-1}(\alpha) \cap \alpha$.

\[ \square \]

For $x \in C$, let us define a continuous horizontal cone field $K^h(x) \equiv K_{\bar{\epsilon}}^h(x)$ whose boundary lines have slopes with the absolute value $s(x)$ such that:
(o) $\mathcal{K}^h(x) \supset \mathcal{K}^{ah}(x)$ everywhere;

(i) $\mathcal{K}^h(x) = \mathcal{K}^{ah}(x)$ in the white region $\mathcal{C} \setminus \mathcal{V}'$ (see Figure 6.5);

(ii) $s(x) \sim |x|/3$ in the grey region $\mathcal{U}'$;

(iii) $s(x) = \bar{w} := \sqrt{\tau(2 - \tau)} \sim \bar{\varepsilon}/3$ in the black region $\mathcal{V} \setminus \mathcal{U} = \mathcal{V}' \setminus \mathcal{U}'$.

Conditions (o)–(ii) are compatible due to (6.3). For a cone field satisfying these three conditions, we have $s(x) = s_0$ on the horizontal boundary of the black region and $s(x) \sim \bar{\varepsilon}/3$ on the vertical one. Hence it can be extended to the black region satisfying (iv).

Note that in $\mathcal{C} \setminus \mathcal{V}$, we have $s^a(x) = \sqrt{\tau(2 - \tau)} \geq \bar{w}$. Hence

$$s(x) \geq \bar{w} \sim \bar{\varepsilon}/3 \quad \text{in} \quad \mathcal{C} \setminus \mathcal{U}.$$  

**Lemma 6.6.** For sufficiently small $\bar{\varepsilon} > 0$, the cone field $\mathcal{K}^h$ is strictly forward invariant:

$$\mathcal{R}(\mathcal{K}^h(x)) \subseteq \mathcal{K}^h(\mathcal{R}x).$$

**Proof.** For $x \in \mathcal{C} \setminus \mathcal{V}'$, we make use of the invariance of the algebraic cone field and conditions (o) and (i):

$$\mathcal{R}(\mathcal{K}^h(x)) = \mathcal{R}(\mathcal{K}^{ah}(x)) \subseteq \mathcal{K}^{ah}(\mathcal{R}x) \subset \mathcal{K}^h(\mathcal{R}x).$$

So, assume $x \in \mathcal{V}'$. The cones $\mathcal{K}^h(x)$ are bounded by two lines spanned by the tangent vectors $v_{\pm} = (1, \pm s(x))$. Let us estimate the absolute value $s'$ of the slope of $D\mathcal{R}(v_{\pm})$.

Select $\bar{\varepsilon}$ so small that (B.8) applies in $\mathcal{U}$. For $x \in \mathcal{U}'$, it yields:

$$s' \leq \frac{|\varepsilon| \tau(\tau + \bar{\varepsilon}^2/3)}{\sigma^2(\tau + 2\bar{\varepsilon}^2/3)} = \frac{|\varepsilon| \tau}{\sigma^2} < |\kappa| < \bar{\varepsilon}/18 < \bar{w}.$$

By Lemma 6.5, $\mathcal{R}x \notin \mathcal{U}$, so property (6.4) ensures (6.5).

Let $x = (\phi, \tau) \in \mathcal{V}' \setminus \mathcal{U}'$. Then for $\bar{\varepsilon}$ sufficiently small, we have:

$$|\cos \phi| \geq \bar{\varepsilon}/2, \quad |\tan \phi| < 4/(3\bar{\varepsilon}), \quad \text{and} \quad \tau \leq \bar{\tau} \leq \bar{\varepsilon}^2/18.$$

Letting $(a, b) = D\mathcal{R}(v_{\pm})$, we obtain from (B.7):

$$a \geq 2 - 2 \tan \phi \cdot \bar{\varepsilon}/3 \geq 10/9 > 1$$

and

$$|b| \leq \frac{2\bar{\varepsilon}^2}{\cos^2 \phi} + \frac{\tau \bar{\varepsilon}}{3 \cos^2 \phi} \leq 16 \frac{\bar{\varepsilon}^2}{\bar{\varepsilon}^2} + 2 \frac{\bar{\varepsilon}}{\bar{\varepsilon}} \leq \left( \frac{16}{18} + \frac{2}{18} \right) \bar{\varepsilon} < \frac{\bar{\varepsilon}}{6}.$$

So, the slope $s' = |b/a| < \bar{w}$ as well. Due to property (6.4), this implies (6.5) in case $\mathcal{R}x \notin \mathcal{U}$.

Finally, let $x \in \mathcal{V}' \setminus \mathcal{U}'$ and $\mathcal{R}x = (\tau', \phi') \in \mathcal{U}$. Then Lemma 6.5 b) gives $|\cos \phi| > C^{-1} > 0$ and $|\tan \phi| < C$, independent of $\bar{\varepsilon}$. Estimate (6.7) simplifies to

$$|s'| \leq |b| = O(\tau^2 + \tau \bar{\varepsilon}) = o(\tau) = o(\sqrt{\tau})$$

as $\bar{\varepsilon} \to 0$.

But $s(\mathcal{R}x) \geq \sqrt{\tau}$ as follows from condition (o). This concludes the proof. \(\square\)

The horizontal cone field $\mathcal{K}^h$ extends continuously to the indeterminacy points as degenerate cones $\mathcal{K}^h(\alpha_{\pm}) = \{d\tau = 0\}$. Obviously, this continuous extension is invariant.
We will also call an smooth path $\gamma(t)$ in $C$ horizontal if at each point $\gamma(t) \in \text{int } C$ we have $\gamma'(t) \in K^h(\gamma(t))$. In the remainder of the paper, all horizontal paths will considered with respect to $K^h$ (and not $K^{ah}$), unless otherwise specified.

Remark 6.3. One obtains a pushed forward cone field $K^h := D\Psi K^h$ on $C$ that is invariant under $R$ and non-degenerate away from $a_\pm$.

6.3. Vertical cone fields and laminations. In this section we develop a language adopted, for definiteness, to the modified cone field $K^h$ on the cylinder $C$, but a similar language, with obvious adjustments, can be applied to the algebraic cone field $K^{ah}$, as well as the corresponding cone fields on the Möbius band $C$.

We let $K^c(x) = T_x C \setminus K^h(x)$ be the complementary vertical cone field. (In particular, $K^c(\alpha_\pm) = \{d\phi \neq 0\}$ is the complement to the horizontal line.)

Let $K(x) \subset K^c(x)$ be a continuous cone field on $C$. Let us define the pullback $DR^*(K)$ as follows. Let $y = Rx$. When $DR_x$ is well defined and invertible (i.e., $x \notin B \cup T \cup I_{\pm\pi/2}$, we let $DR^*(K)(x) = DR_x^{-1}(K(y))$. When $DR_x$ is well defined but is not invertible, we let $DR^*(K)(x) = \ker DR_x$. Finally, for $x \in \{\alpha_\pm\}$ we let $DR^*(K)(x) = K^v(\alpha_\pm)$.

It is easy to see that the pullback is continuous (and is contained in $K^v$).

Corollary 6.7. The vertical cone field $K^v$ is backwards invariant: $DR^*(K^v) \subset K^v$.

In this setting, “vertical paths” are understood in the sense of the vertical cone field $K^v$ rather than $K^{av}$. So, by definition, a vertical path\(^{21}\) is a smooth path $\gamma(s)$ in $C$ such that $\gamma'(s) \in K^h(\gamma(s))$. Being a graph over a temperature interval, it can be parameterized accordingly: $\phi = \gamma(t)$. Moreover, $\gamma'(s)$ is finite except possibly at the indeterminacy points $\alpha_\pm = \gamma(1)$ (if $\gamma$ terminates at one of them).

A vertical lamination $F$ in $C$ is a family of vertical paths (the leaves of the lamination) which are disjoint in the topless cylinder $C_1$ (but are are allowed to meet on $T$) that has a local product structure. The latter means that for any path $\gamma_0 \in F$ and any point $x_0 = (\gamma_0(t_0), t_0) \in C_1$ there exists an $\epsilon > 0$ such that any leaf $\gamma \in F$ passing near $x_0$ can be locally represented as a graph over $(t_0 - \epsilon, t_0 + \epsilon)$, and this graph depends $C^1$-continuously on the transverse parameter $\phi = \gamma(t_0)$. The supp($F$) is the union of the leaves of the lamination.

A vertical lamination is called proper if all its leaves are proper.

For instance, a finite family of disjoint proper vertical paths form a proper vertical lamination.

In case when supp $F$ is open in $C_1$, the lamination $F$ is called a strictly vertical foliation (of its support). For instance, the “genuinely vertical” foliation on the cylinder $C_1$ is formed by the intervals $I_\phi$, $\phi \in \mathbb{R}/2\pi\mathbb{Z}$.

Lemma 6.6 implies that the pullbacks $(R^v)^*(F)$ of a (proper) vertical lamination are (proper) vertical.

We will mostly be dealing with laminations whose leaves begin on the bottom of the cylinder (in fact, mostly with proper laminations), and will use the bottom angle $\phi \in \mathbb{Z}/2\pi\mathbb{Z}$ as the transverse parameter, $\gamma = \gamma_\phi$.

---

\(^{21}\)In the remainder of the paper, all vertical paths will be considered with respect to $K^v$ (and not $K^{av}$) unless otherwise specified.
7. Central line field and dominated splitting

In this section we will use the cone field constructed in §6 to prove that \( \mathcal{R} : \mathcal{C} \to \mathcal{C} \) is projectively hyperbolic, or admits a dominated splitting. We will start with constructing an invariant vertical line field.

7.1. Central line field. A central line field \( \mathcal{L} \) on \( \mathcal{C} \) is an \( \mathcal{R} \)-invariant continuous tangent line field \( \mathcal{L}(x) \subset K_v(x) \), \( x \in \mathcal{C} \setminus \{ \alpha_{\pm} \} \). Here “invariance” means that \( DR_x(\mathcal{L}(x)) \subset \mathcal{L}(Rx) \) whenever \( x \notin \{ \alpha_{\pm} \} \cup \mathcal{R}^{-1}\{ \alpha_{\pm} \} \).

Proposition 7.1. There exists a unique central line field on \( \mathcal{C} \). Moreover, if \( \mathcal{L}(x) \subset K_v(x) \) is any vertical line field then

\[
(DR^n)^* \mathcal{L} \to \mathcal{L}^c
\]

uniformly and exponentially on compact subsets of \( \mathcal{C} \setminus \{ \alpha_{\pm} \} \).

7.1.1. Hyperbolic metric. To prove this proposition, we will make use of the “projective hyperbolic metric” on the vertical cones. Any interval \( I = (a,b) \subset \mathbb{R} \) can be viewed as the hyperbolic line endowed with the hyperbolic metric

\[
dist_I(x,y) = \log \frac{y-a}{x-a} + \log \frac{b-x}{b-y}, \quad a < x < y < b.
\]

Since cross-ratios are projective invariants, the hyperbolic metric is invariant under Möbius isomorphisms \( \phi : I \to J \). Moreover, it gets contracted under inclusions: if \( I \subset J \) then

\[
dist_J(x,y) \leq \lambda \dist_I(x,y), \quad x, y \in I,
\]

where \( \lambda < 1 \) depends only on the hyperbolic diameter of \( I \) in \( J \). Putting these two properties together, we obtain the following “Schwarz Lemma” for projective maps:

Lemma 7.2. Let \( \phi : I \to J \) be a Möbius transformation with \( \phi(I) \subset J \). Then

\[
dist_J(\phi(x), \phi(y)) \leq \lambda \dist_I(x,y), \quad x, y \in I,
\]

where \( \lambda < 1 \) depends only on the hyperbolic diameter of \( \phi(I) \) in \( J \).

Due to projective invariance, the above discussion can be carried to any intervals \( I, J \) in the projective line \( \mathbb{P}\mathbb{R}^1 \).

7.1.2. Contraction of the projective cone field. As the cones \( K^v(x) \) represent intervals in the projective tangent lines, they can be endowed with the hyperbolic metrics \( d_x \).

Lemma 7.3. For any neighborhood \( U \) of the indeterminacy points \( \{ \alpha_{\pm} \} \), there exist \( C > 0 \) and \( \lambda > 1 \) such that for any \( x \in \mathcal{C} \setminus U \)

\[
diam(DR^n)^*(PK^v)(x) \leq C\lambda^{-n},
\]

where the \( \text{diam} \) stands for the angular size of the cones.

Proof. By Lemma 7.2, the differential \( DR^{-1} : PK^v(Rx) \to PK^v(x) \) contracts the hyperbolic metric by a factor \( \mu(x) < 1 \) depending only on the hyperbolic diameter of \( DR^*(PK^v)(x) \) in \( PK^v(x) \). (For a critical point \( x \), the projective cone \( DR^*(PK^v)(x) \) collapses to a point, and we let \( \mu(x) = 0 \).) By continuity of the cone fields, this factor is uniform away from \( U \). Since the \( \alpha_+ \) blow up to the curve \( \mathcal{G} \) that does not contain \( \alpha_{\pm} \), the orbit of \( x \) can visit \( U \) with frequency bounded by \( 1/2 \) (provided \( U \) is sufficiently small). Hence the hyperbolic diameter of the cones
(DR^m)^*(PK^c)(x) decay exponentially with rate O(\mu^{n/2}). Since the projective intervals PK^c(x) have angular size bounded away from \pi, the diam(DR^m)^*(PK^c)(x) are O of their hyperbolic size, and the conclusion follows. \hfill \square

7.1.3. Proof of Proposition 7.1. Let us take a vertical line field L on C and pull it back by the dynamics: L_n = (DR^n)^*L. By Lemma 7.3, for any m \leq n we have:
\[ \text{dist}(L_n(x), L_m(x)) \leq C\lambda^{-m}, \quad x \in C \setminus U. \]
Hence the L_n uniformly and exponentially converge to a limit, which is the desired central line field L^c. \hfill \square

7.2. Dominated splitting. We say that the horizontal cone field K^h and central line field L^c give a dominated splitting of the map R : C \to C if for any neighborhood U of the indeterminacy points \alpha_{\pm}, there exist constants c > 0 and \lambda > 1 such that for any two tangent vectors v^h \in K^h(x) and v^c \in L^c(x) of unit length we have:
\[ \|DR^n v^h\| \geq c\lambda^n\|DR^n v^c\|, \quad x \in C \setminus U. \]
(In other words, horizontal vectors grow exponentially faster than the central ones.)

Remark 7.1. For diffeomorphisms, the splitting is usually given by two sub-bundles of the tangent bundle (see [Pu]). However, such a definition is not suitable for the non-invertible case when the unstable sub-bundle may not exist. That is why we give a definition in terms of cone fields. Of course, in the invertible case, both definitions are equivalent.

Lemma 7.4. For any x \in C \setminus \{\alpha_{\pm}\} and i \geq 3, if v_1, v_2 \in DR^i(K^h(x)) satisfy v_1 - v_2 \in L^c(R^ix), then \|v_1\| > \|v_2\|.

Proof. Let U be a neighborhood of {\alpha_{\pm}} chosen sufficiently small so that if x \in U then R^nx \not\in U for n = 1, 2. Lemma 7.2 implies that DR^i(PK^h(x)) has uniformly bounded hyperbolic diameter for i \geq 3. Let L_1 and L_2 be any two lines through DR^i(PK^h(x)) and let \theta(L_1, L_2), \theta(L_1, L^c), and \theta(L_2, L^c) be the angles between them and between each line and L^c \equiv L^c(x). The uniform bound on the hyperbolic diameter implies that there is some constant C > 0 so that
\[ \theta(L_1, L_2) \leq C \cdot \theta(L_j, L^c), \quad j = 1, 2. \]
The result then follows from basic trigonometry. \hfill \square

Corollary 7.5. For any neighborhood U of {\alpha_{\pm}} and any x \in C \setminus U, if v^h_1, v^h_2 \in K^h(x) are unit tangent vectors then \|DR^n v^h_1\| > \|DR^n v^h_2\|.

Proof. Since x \not\in U, the projection of v^h_1 onto v^h_2 along L^c will have length comparable to the length of v^h_2. Thus, the result follows for n \geq 3 from Lemma 7.4. If n \leq 2, the result follows from the fact that DR can only contract a horizontal vector by a bounded amount (Lemma B.3). \hfill \square

Note that Corollary 7.5 implies that condition (7.1) is in fact independent of the particular choice of v^h.

Proposition 7.6. The horizontal cone field K^h and central line field L give a dominated splitting of the map R : C \to C.
Proof. Since a single iterate of $R$ can only contract horizontal vectors by a bounded amount (Lemma B.3), it suffices to consider $n \geq 3$. Let $x_n := R^n x$ be the orbit of any $x \in C \setminus U$. Let $v^h(x_n)$ be the unit vector on the boundary of $D(R^3(K^h(x_n-3)))$ pointing “northeast” and let $v^c(x_n)$ be the unit central vector pointing “north”. By definition, the vector
\begin{equation}
   w_n = v^h(x_n) + v^c(x_n)
\end{equation}
will satisfy $(DR^3)^* w_n \in K^v(R^{n-3}x)$.

We pull back $w_n$ under the dynamics and decompose it as
\begin{equation}
   (R^n)^* w_n := w = w^h + w^c
\end{equation}
with $w^h$ parallel to the unit vector on the boundary of $K^h(x)$ pointing “northeast” and $w^c \in \mathcal{L}^c(x)$. By Proposition 7.1,
\begin{equation}
   \|w^c\| \geq c\lambda^n \|w^h\|.
\end{equation}

But
\begin{equation}
   w_n = R^n(w^h) + R^n(w^c) \text{ with } R^n(w^h) \in D(R^3(K^h(x_n-3))), \ R^n(w^c) \in \mathcal{L}^c.
\end{equation}
Since $R^n(w^h)$ and $v^h(x_n)$ differ by an element of $\mathcal{L}^c(x_n)$, Lemma 7.4 gives
\begin{equation}
   \|R^n(w^h)\| \approx \|v^h(x_n)\| = 1,
\end{equation}
and hence $\|R^n(w^c)\| = \|w_n - R^n(w^h)\| = O(1)$. We see that $\|R^n(w^h)\|/\|R^n(w^c)\|$ is bounded from below, and hence (7.3) can be written as
\begin{equation}
   \frac{\|R^n(w^h)\|}{\|R^n(w^c)\|} \geq c\lambda^n \frac{\|w^h\|}{\|w^c\|}
\end{equation}
But this is just the homogeneous form of the dominated splitting condition (7.1). Since this condition is independent of the particular choice of vectors $w^h$ and $w^c$, we are done.

7.2.1. Central curves. Let us say that a smooth curve is central it is tangent (on $C \setminus \{\pm\}$) to the central line field $\mathcal{L}^c$.

Proposition 7.7. Through any point $x \in C \setminus \{\pm\}$ passes a vertical central curve.

Proof. It follows from the Peano Existence Theorem (see [W]) that continuous line fields are integrable, so we can find a central curve through any point $x \in C \setminus \{\pm\}$. Since the central line field is transverse to the genuinely horizontal foliation, this curve is a graph over the t-axes, and for standard reasons can be extended in both ways to the boundary of the cylinder. This is the desired vertical central curve.

If $x \in \{\pm\}$, then one can take $I_{\pm}$ as the desired central curve. (In fact, there are whole central tongues $\Lambda_{\pm}$ filled with vertical central curves landing at $\alpha_{\pm}$ – see §12.1.)

Remark 7.2. At this stage we do not know yet that there exists a unique central curve through a given $x$. In fact, as we have just mentioned, this is not the case for the indeterminacy points $\alpha_{\pm}$ (and hence for their preimages). However, we will prove in §12.1 that the uniqueness holds on $C_1$. 

8. Horizontal expansion

In this section we will prove that the map $\mathcal{R} : \mathcal{C} \to \mathcal{C}$ is *horizontally expanding*, in the following sense:

- $\mathcal{R}$ has an invariant horizontal cone field $\mathcal{K}^h(x)$ on $\mathcal{C} \setminus \{\alpha_\pm\}$;
- There exist constants $c > 0$ and $\lambda > 1$ such that
  \[ |D\mathcal{R}^n(x)(v)| \geq c\lambda^n|v|, \quad n = 0, 1, \ldots \]
for any $x \in \mathcal{C} \setminus \{\alpha_\pm\}$ and $v \in \mathcal{K}^h(x)$. Moreover, $\lambda$ is called a *rate of expansion*.

**Theorem 8.1.** The map $\mathcal{R} : \mathcal{C} \to \mathcal{C}$ is horizontally expanding on $\mathcal{C}$ with the rate $\lambda = 2$ with respect to the horizontal cone field $\mathcal{K}^h$ from §6.2.

8.1. **Global Approach.** Let us consider the solid cylinder

$$ SC := \{(z, t) : |z| \leq 1, \quad t \in [0, 1]\}. $$

It is foliated by the horizontal leaves

$$ \Pi_t^* := \{(z, t) : |z| \leq 1, \quad t \in [0, 1]\}. $$

In the $(u, w)$-coordinates, the horizontal complex lines $\Pi_t := \{(z, t) : z \in \mathbb{C}\}$ correspond to the conics $P_t = \{|uw| = t^{-2}\}$, and the leaves of the solid cylinder become

$$ P_t^* := \{(u, w) \in P_t : |u| \geq t^{-1}\}, \quad t \in [0, 1]. $$

Here the bottom leaf $P_0^*$ is the complement of the unit disk, $\mathbb{C}P^1 \setminus D$, in the coordinate $\zeta = u/w$ on the line at infinity $L_0 = \{V = 0\} \approx \mathbb{C}P^1$.

Recall that the cylinder $C$ itself (or rather, the Möbius band) is given by

$$ C = \{w = \bar{u}, \quad |u| \geq 1\}, $$

see §3.1. The leaf $P_t^*$ intersects it by the round circle $S_t = \{|u| = t^{-1}\}$. All the leaves $P_t^*$ meet at the attracting fixed point $e = (1 : 0 : 0)$ at infinity.

Let us now consider the central projection from the origin to the line $L_0$ at infinity:

$$ \pi : \mathbb{C}P^2 \to L_0 \quad (u, w) \mapsto \zeta = u/w. $$

**Lemma 8.2.** For any $t \in [0, 1)$, the map

$$ (8.1) \quad \psi_n = \pi \circ R^n : P_t^* \to P_0^* $$

is a branched covering of degree $2 \cdot 4^n$.

**Proof.** We fix some $t \in [0, 1)$, and skip it from the notation, so $P^* \equiv P_t^*$, etc. Since $R$ is algebraically stable, Lemma A.6 gives that the push-forward $(R^n)_*P$ is a divisor of degree $4^n \cdot 2$.

Bezout’s Theorem gives $4^n \cdot 2$ intersections of $(R^n)_*P$ with with the complexification of any radial line $L := \{\arg u = \phi \mod \pi\}$. However, the Möbius band $C$ is in invariant and $R$ acts with degree 4 on its first homology, so that $R^n(P \cap C)$ is a horizontal curve of degree $4^n$ on $C$, forcing all $4^n \cdot 2$ intersections take place in $C = \{|u| \geq 1\}$. In particular $(R^n)_*P$ does not pass through the origin $u = w = 0$ so that the central projection $\pi : R^n(P) \to B$ is well defined, and is a degree $2 \cdot 4^n$ branched covering.

Furthermore, $\pi : R^n(P) \cap C \to B$ is also a degree $2 \cdot 4^n$ covering so that $\psi_n : P \to L_0$ is a rational map between two Riemann spheres of degree $2 \cdot 4^n$ (commuting with the natural antiholomorphic involutions) that restricts to a covering map between
the circles \( P \cap C \rightarrow B \) (the fixed points loci for the involutions) of the same degree. By the Argument Principle, any point \( \zeta \in P^*_0 \) has at least \( 2 \cdot 4^n \) preimages in the disk \( P^* \).

\[ \square \]

Let us now consider the fixed point \( e \) at the center of the both disks \( P_t \) and \( P_0 \).

**Lemma 8.3.** The map \( \psi_n \) has branching of degree \( 2n^2 + 2 \) at \( e \).

**Proof.** Use local coordinates \((v = V/U, w = W/U)\) near \( e = (1 : 0 : 0) \). In these coordinates, the map \( R \) assumes the form

\[
(8.2) \quad v' = v^2 \left( \frac{1 + w}{1 + v^2} \right)^2 \sim v^2, \quad w' = \left( \frac{w^2 + v^2}{1 + v^2} \right)^2 \sim v^4 (1 + (w/v)^2)^2,
\]

while the curve \( P \) becomes the parabola \( w = v^2 \). Let us use \( s = v \) as a local parameter for \( P \). Then all the images \( R^n(P) = (v_n(s), w_n(s)) \) are naturally parameterized by \( s \) as well, and (8.2) imply inductively:

\[
v_n \sim s^{2n+1}, \quad w_n \sim s^{2n+2}.
\]

Hence given a small \( w_n \), we find \( 2n^2 + 2 \) parameter values \( s \) near the origin such that \( \psi_n(s) = w_n \), and the conclusion follows. \[ \square \]

**Remark 8.1.** Note that because of the symmetry \( R(-u, -w) = R(u, w) \), the images \( R^n(P) \) are covered twice by \( P \). If we consider \( R^n(P) \) as a divisor of multiplicity two, then its order of tangency with the \( u \)-axis at \( e = (\infty, 0) \) is \( 2n + 2 \). But if we treat \( R^n(P) \) as a simple curve then the order of tangency is twice smaller.

**Lemma 8.4.** The Blaschke product \( B \) vanishing at the origin to order \( k \) expands the Euclidean metric on the circle \( \mathbb{T} \) at least by \( k \).

**Proof.** Under the circumstances,

\[
B(z) = z^k \hat{B}, \quad \text{where } \hat{B} \text{ is another Blaschke product.}
\]

In the angular coordinate \( z = e^{i\phi} \) it assumes a form

\[
\phi \mapsto k\phi + h(\phi),
\]

where \( h'(\phi) > 0 \) since \( \hat{B} \) is orientation preserving on the circle. The assertion follows. \[ \square \]

**Proof of Theorem 8.1.** Let us uniformize \( P \) by the Riemann sphere so that the \( P \cap C \) becomes the unit circle \( \mathbb{T} = \{ |\lambda| = 1 \} \). Lemma 8.2 implies that in this coordinate, the map \( \zeta = \psi_n(\lambda) \) becomes a Blaschke product. By Lemma 8.3, it vanishes of order \( 2n + 2 \) at the origin. By Lemma 8.4, it expands the circle metric at least by factor \( 2n + 2 \). Hence \( R^n \) expands the cylinder metric along \( P \cap C \) at least by \( c2^{n+2} \) with some \( c > 0 \).

But then the same is true for any \( v \in K^h(x), x \in C \). If \( N \) is any small neighborhood of the indeterminate points \( a_\pm \), then all horizontal vectors \( v \in K^h(x) \) that are equivalent mod \( \mathcal{L}^e \) have a comparable length (uniformly over \( x \in C \setminus N \)). Corollary 7.5 then gives that the lengths of the iterated vectors remain comparable.

Finally, if \( x \in N \), then Lemma B.3 gives that one iterate of \( R \) can contract the horizontal length only by a bounded factor and the result follows. \[ \square \]
8.2. Combinatorial Approach. We will now present another proof of Theorem 8.1 that is based on a combinatorial interpretation of the DHL and the Lee-Yang Theorem with Boundary Conditions. The notation is from §2.1.

Recall that the partition function of the Ising model on $\Gamma_n$ is given as
\begin{equation}
Z_n = \sum_{\sigma} e^{-H_n(\sigma)/T} = \sum_{\sigma} t^{-I(\sigma)/2} z^{-M(\sigma)},
\end{equation}
where $M(\sigma)$ and $I(\sigma)$ are the magnetic moment (2.1) and interaction (2.2) of the configuration $\sigma$. Let $\sigma_+ \equiv +1$ and $\sigma_- \equiv -1$. Clearing denominators we obtain the modified partition function
\begin{equation}
\tilde{Z}_n(z) := t^{I(\sigma_-)} z^{4n} Z_n(z) = \sum_{j=0}^{N} a_j z^j,
\end{equation}
with $N = 2 \cdot 4^n$. Recall the basic symmetry of the Ising model
\[ a_{N-j} = a_j, \quad j = 0, 1, \ldots, N; \quad a_0 = a_N = 1, \]
which is obtained under the involution $\sigma \mapsto -\sigma$ and from the invariance $I(\sigma) = I(-\sigma)$.

The generating graph $\Gamma$ is symmetric under reflection across the vertical line through the marked vertices $a$ and $b$. This allows us to factor\footnote{\(V_n\) also factors, but will not use it.} the conditional partition functions $U_n$ and $W_n$ as
\[ U_n = U_n^2 \quad W_n = W_n^2, \]
where $U_n$ and $W_n$ correspond to the conditional partition functions of the right (or left) half of $\Gamma_n$, having the same boundary conditions as $U_n$ and $W_n$.

Both halves of $\Gamma_n$ have valence $2^n-1$ at $a$ and $b$. In particular, if $\sigma(a) = \sigma(b) = +1$, there are at most $4^n/2 - 2^n$ edges both of whose endpoints have spin $-1$. This gives that $U_n$ has no terms in $z$ of degree greater than $4^n/2 - 2^n$. Similarly, $W_n$ has no terms in $z$ of degree lower than $-4^n/2 + 2^n$.

Clearing denominators, one obtains
\begin{align*}
\hat{U}(z) &:= t^{I(\sigma_+)/2} z^{4^n/2} U(z) = \sum_{j=0}^{N_0} a^+_j z^j \\
\hat{W}(z) &:= t^{I(\sigma_-)/2} z^{4^n/2 - 2^n} W(z) = \sum_{j=0}^{N_0} a^-_j z^j,
\end{align*}
where $N_0 = 4^n - 2^n$. It follows from the Lee-Yang Theorem with Boundary Conditions that the zeros $b_1, \ldots, b_{N_0}$ of $\hat{W}(z)$ all lie in $\mathbb{D}$.

The basic symmetry of the Ising model appears as the following symmetry between $\hat{U}$ and $\hat{W}$:
\[ a^-_{N_0-j} = a^+_j, \quad j = 0, 1, \ldots, N_0. \]
Consequently,
\[ \hat{W}_n(z) = \prod_{j=1}^{N_0} (z - b_j) \quad \text{and} \quad \hat{U}_n(z) = \prod_{j=1}^{N_0} (1 - b_j z) = \prod_{j=1}^{N_0} (1 - \bar{b}_j z), \]
using also that $\tilde{U}_n(z)$ has real coefficients.

Since $z_n^2 = W_n/U_n = \frac{W_n^2}{U_n^2}$, we obtain the Blaschke Product

\begin{equation}
 z_n = \frac{W_n}{U_n} = z^{2^n} \frac{\tilde{W}_n}{\tilde{U}_n} = z^{2^n} \prod_{j=1}^{N_0} \frac{z - b_j}{1 - b_j z}
\end{equation}

having all of its zeros in $\mathbb{D}$ and a zero at $z = 0$ of multiplicity $2^n$.

**Remark 8.2.** The degree of (8.5) is half of the degree for the Blaschke product in terms of $u$ and $v$ that was obtained using the global approach because of the relationship $z^2 = W/U$. This is why the multiplicity of $z = 0$ in (8.5) is only $2^n$ instead of $2^{n+1}$.

The remainder of the proof continues as in §8.1.

9. LOW TEMPERATURE DYNAMICS: BASIN OF $\mathcal{B}$ AND ITS STABLE FOLIATION

The bottom circle $\mathcal{B}$ is superattracting within $\mathcal{C}$ by Property (P5) from §3.1, so there is an open set $W^\alpha(\mathcal{B}) \subset \mathcal{C}_1$ consisting of points whose orbits converge to $\mathcal{B}$, called the basin of attraction of $\mathcal{B}$. Obviously, $W^\alpha(\mathcal{B})$ is completely invariant under $\mathcal{R}|\mathcal{C}_1$.

9.1. Low temperature cylinder $\mathcal{C}_*$. Recall that $t_c$ is height of the real repelling fixed point $\beta_c$ in the invariant line $\{\phi = 0\}$, and let $\beta'_c = (\pi, t_c)$,

$$
\mathcal{C}_* = \{ (\phi, t) \in \mathcal{C} : t \leq t_c \}.
$$

We will call $\mathcal{C}_* \setminus \{ \beta_c, \beta'_c \}$ the low temperature cylinder.

Let us begin with a simple observation:

**Lemma 9.1.** The basin $W^\alpha(\mathcal{B})$ contains the low temperature cylinder $\mathcal{C}_* \setminus \{ \beta_c, \beta'_c \}$.

**Proof.** We will check that points $x \in \mathcal{C}_* \setminus \{ \beta_c \}$ converge to the bottom $\mathcal{B}$ at least as fast as they do on the low temperature interval $(\beta_0, \beta_c) \subset \mathcal{I}_0$.

For $x = (\phi, t) \in \mathcal{C}$, we let $t(x) = t$. Since the function

$$
 y \mapsto \frac{y + 1}{y + s}
$$

is non-increasing on $(-1, 1]$ for $s \geq 1$, (3.3) gives that $t(\mathcal{R}x) \leq t(\mathcal{R}(0, t(x)))$, with equality attained only if $x \in \mathcal{I}_0, \mathcal{I}_z$.

Let $t_n = t(\mathcal{R}^n x)$ and let $q_n = t(\mathcal{R}^n(0, t_0))$. By the above observation, if $x \in \mathcal{C}_* \setminus \{ \beta_c \}$ then $t_1 < t_c$, and furthermore, $t_{n+1} \leq q_n \to 0$ as $n \to \infty$. Thus, $\mathcal{C}_* \setminus \{ \beta_c \} \subset W^\alpha(\mathcal{B})$. \hfill $\square$

9.2. Complex stable lamination of $\mathcal{B}$ in $\mathbb{C}^2$. In $\mathbb{C}^2$, the circle $\mathcal{B}$ is hyperbolic, with a complex one-dimensional transverse stable direction (the $t$-direction) and a real one-dimensional transverse unstable one (the unstable direction within the plane $t = 0$).

Given an $\epsilon > 0$, the $\epsilon$-local basin $W^\alpha_{\epsilon, \phi}(\mathcal{B})$ is the set of points $\zeta \in \mathbb{C}^2$ that are $\epsilon$-close to $\mathcal{B}$ and whose orbits converge to $\mathcal{B}$ while remaining $\epsilon$-close to $\mathcal{B}$. Alternatively, we can use any forward invariant open set containing $\mathcal{B}$ to define a local stable set $W^s_{\mathcal{C}, \text{loc}}(\mathcal{B})$, with the specific open set that is used implicit in the notation.

Similarly, for $x = (\phi, 0) \in \mathcal{B}$, a local stable manifold $W^s_{\mathcal{C}, \text{loc}}(x) = W^s_{\mathcal{C}, \text{loc}}(\phi)$ is a 1-dimensional holomorphic curve containing $x$ consisting of all points $\zeta$ near $x$
whose orbits are forward asymptotic to the orbit of \( x \), while remaining close to the orbit of \( x \).

In this subsection we will construct the local stable lamination \(^{23}\) of the bottom circle \( \mathcal{B} \) in \( \mathbb{C}^2 \) and will show that the leaves \( \mathcal{W}_{\mathcal{B}, \text{loc}}(\phi) \), \( \phi \in \mathbb{T} \), of this lamination are holomorphic curves filling in a topological real 3-manifold contained within \( \mathcal{W}_{\mathcal{B}, \text{loc}}(\mathcal{B}) \).

In the case of diffeomorphisms, the construction of the stable laminations for hyperbolic sets is a standard background of the general theory, see [HPS, PM, Sh]. However, we have not been able to find an adequate reference in the non-invertible case (notice, however, the remark in [PM, p. 79]), so we will give a direct argument in our situation.

We will make use of the simple structure of the postcritical locus near \( \mathcal{B} \) (comprising two lines \( \{ t = \pm \pi/2 \} \) collapsing to the fixed point \( \beta_0 \)) and of the holomorphic \( \lambda \)-lemma. This is similar to the method used in [HP, §2.4] and [R, §4].

**Proposition 9.2.** For sufficiently small \( \epsilon > 0 \), local stable manifolds \( \mathcal{W}_{\mathcal{B}, \text{loc}}^n(x) \), \( x \in \mathcal{B} \), are holomorphic curves whose union \( \bigcup_{x \in \mathcal{B}} \mathcal{W}_{\mathcal{B}, \text{loc}}^n(x) \) form a lamination supported on the local basin of \( \mathcal{W}_{\mathcal{B}, \text{loc}}(\mathcal{B}) \). Moreover, \( \bigcup_{x \in \mathcal{B}} \mathcal{W}_{\mathcal{B}, \text{loc}}^n(x) \) is a topological real 3-manifold.

**Proof.** Let \( \mathcal{Q} \subset \mathcal{B} \) be the set of iterated preimages of 1 under \( z \mapsto z^4 \). We will construct a family of analytic discs \( \mathcal{D}_z \) through the the set \( \mathcal{Q} \) in such a way that each disc intersects \( \mathcal{B} \) in exactly one point \( z \in \mathcal{Q} \) and so that \( \mathcal{D}_z \) is obviously the stable disc of \( z \). We will furthermore verify that each \( \mathcal{D}_z \) can be expressed as the graph of a function \( z = \eta(t) \) for all \( t \) in an appropriate small disc \( \mathcal{D}_\rho \).

This family of discs provides a holomorphic motion of \( \mathcal{Q} \), parameterized by \( \mathcal{D}_\rho \):

\[
\mathcal{h} : \mathcal{Q} \times \mathcal{D}_\rho \to \mathbb{C}.
\]

Then, the \( \lambda \)-Lemma [Ly, MSS] for holomorphic motions immediately gives that \( \mathcal{h} \) extends to the closure providing a continuous mapping \( \bar{\mathcal{h}} : \mathcal{B} \times \mathcal{D}_\rho \to \mathbb{C} \).

Recall that the line \( t = 0 \) is superattracting away from the origin. Therefore, choosing \( 0 < a < 1 \) and \( C > 0 \) we can easily further restrict \( \rho > 0 \) so that \( |t_n| \leq C a^n \) for any choice of \( (z, t) \in \cup_{t \in \mathcal{Q}} \bar{\mathcal{D}}_z \). (Here \( t_n = t(\mathcal{R}^n(z, t)) \).) Therefore, points in the closure, and in particular, points in the image of \( \mathcal{B} \times \mathcal{D}_\rho \) under \( (\phi, t) \mapsto (\bar{\mathcal{h}}(\phi, t), t) \) converge at least geometrically to \( \mathcal{B} \).

Given \( (\phi, 0) \in \mathcal{B} \), the stable leaf \( \mathcal{W}_{\mathcal{B}, \text{loc}}^n(\phi) \) is parameterized by \( t \mapsto (\bar{\mathcal{h}}(\phi, t), t) \) for \( |t| < \rho \). The union of all stable leaves, which is given by the image of \( \mathcal{B} \times \mathcal{D}_\rho \) under \( (\phi, t) \mapsto (\bar{\mathcal{h}}(\phi, t), t) \), is the desired lamination. It is contained within \( \mathcal{W}_{\mathcal{B}, \text{loc}}(\mathcal{B}) \) by the discussion in the previous paragraph.

We now construct the holomorphic motion \( \mathcal{h} : \mathcal{Q} \times \mathcal{D}_\rho \to \mathbb{C} \).

Consider a neighborhood \( \Delta_{\delta, \rho} \) of \( \mathcal{B} \) of the form

\[
\Delta_{\delta, \rho} = \{(z, t) \in \mathbb{C}^2 : 1 - \delta < |z| < 1 + \delta, \ |t| < \rho \}
\]

Let \( \partial^v \Delta_{\delta, \rho} \) be the vertical boundary \( |z| = 1 \pm \delta \) and \( \partial^h \Delta_{\delta, \rho} \) the horizontal boundary \( |t| = \rho \).

**Lemma 9.3.** We can choose \( \delta, \rho > 0 \) sufficiently small so that

\(^{23}\)Here, a lamination is a family of disjoint holomorphic curves that has a local product structure, in a sense similar to that given in §6.3.
(1) The complex vertical cone-field $|dt(v)| > |dz(v)|$ is backward invariant under $\mathcal{R}$.

(2) $\mathcal{R}(\partial^v \Delta_{\delta,\rho})$ is entirely outside of $\Delta_{\delta,\rho}$ and $\mathcal{R}(\partial^h \Delta_{\delta,\rho})$ is entirely contained within $|t| < \rho$.

Proof. On $\mathcal{B}$ we have

$$DR = \begin{bmatrix} 4z^3 & 0 \\ 0 & 0 \end{bmatrix}$$

so that, by continuity the $(1,1)$ term of $DR$ dominates the remaining terms in any sufficiently small neighborhood of $\mathcal{B}$. This is sufficient for the desired invariance of the conefield in (1).

We now further restrict $\partial^h \Delta_{\delta,\rho}$ so that (2) holds. However, this again follows easily by continuity because on $t = 0$ we have that $\mathcal{R}$ is given by $z \mapsto z^4$ which maps the boundary of any annulus of the form $1 - \delta < |z| < 1 + \delta$ well outside of the annulus and because the line $t = 0$ is superattracting. □

We will call an analytic disc $D$ in $\Delta_{\delta,\rho}$ admissible if:

1. $D$ intersects $\mathcal{B}$ in a single point,
2. $\partial D$ intersects $\partial \Delta_{\delta,\rho}$ only in the vertical boundary $\partial^v \Delta_{\delta,\rho}$, and
3. The tangents to $D$ lie within the vertical cone-field Lemma 9.3 above.

These properties are chosen to ensure that any admissible disc can be written as the the graph of some function $z = \eta(t)$ for some analytic $\eta : \mathbb{D}_\rho \to \mathbb{C}$.

We now construct the family of discs $D_z$ for all $z \in \mathcal{Q}$. We do this “by hand” for the first preimages of 1, letting:

$$D_{\pm1} = \pm1 \times \mathbb{D}_\rho, \text{ and } D_{\pm i} = \pm i \times \mathbb{D}_\rho,$$

because this first level of discs is “delicate” since $D_{\pm i}$ contain portions of the collapsing lines. Note that each is clearly the stable disc of its basepoint, and clearly admissible.

We now inductively define admissible stable discs $D_z$ over any $z \in \mathcal{Q}$, assuming that $z^4 \neq 1$. Suppose that $z$ is an $n$-th preimage of 1. By construction, there is an admissible stable disc $D_{z'}$ over $z' = z^4$, which transversally intersects the critical value locus of $\mathcal{R}$. (Within $\Delta_{\delta,\rho}$ the critical value locus of $\mathcal{R}$ is the union of the line $t = 0$ and the point $(1,0)$.) Therefore, $R^{-1}(D_{z'})$ is a finite union of analytic discs. Let $D_z$ be the component of $R^{-1}(D_{z'}) \cap \Delta_{\delta,\rho}$ containing $z$. By properties (1) and (2) from the lemma, we see that since $D_{z'}$ was an admissible disc, so is $D_z$.

Continuing in this way one defines a family of admissible stable discs over every $z \in \mathcal{Q}$. The result is the desired holomorphic motion $h : \mathcal{Q} \times \mathbb{D}_\rho \to \mathbb{C}$.

The map $(\phi, t) \mapsto (\tilde{h}(\phi, t), t)$ is clearly an immersion of $\mathcal{B} \times \mathbb{D}_\rho$ into $\mathbb{C}^2$ with image $\bigcup_{x \in \mathcal{B}} \mathcal{W}_{\mathbb{C}, \text{loc}}(x)$. Shrinking $\rho$ slightly, if necessary, this immersion can be made into an embedding. □

The $\lambda$-Lemma gives the following regularity for $\bigcup_{x \in \mathcal{B}} \mathcal{W}_{\mathbb{C}, \text{loc}}(x)$. Globally, it is just a topological manifold, however each slice with $t = t_0$ for $|t_0| < \rho$ is the image of the unit circle $\mathcal{B}$ under a quasiconformal homeomorphism with dilatation

$$K \leq \frac{\rho + |t_0|}{\rho - |t_0|} \mathcal{W}_{\mathbb{C}, \text{loc}}(\mathcal{B}).$$
9.3. Stable foliation of \( B \) in the cylinder. Let us now consider the slices of the local stable manifolds by the cylinder,
\[
W^s_{\text{loc}}(x) \equiv W^s_{\text{loc}}(\phi) = W^s_{\text{loc}}(\phi) \cap C, \quad x = (\phi, 0), \quad \phi \in \mathbb{T}.
\]
They are real analytic curves that form a foliation of a neighborhood of \( B \) in \( C \). Note that the \( W^s_{\text{loc}}(\pm \pi/2) \) are arcs of the collapsing intervals \( I_{\pm \pi/2} \).

We will now globalize this foliation. Let \( W^s_n(\phi) \) stand for the lift of \( W^s(4\phi, 0) \) that begins at \((\phi, 0)\). Since \( \mathcal{R}(W^s_{\text{loc}}(\phi)) \subset W^s_{\text{loc}}(4\phi) \), we have:
\[
W^s_{n+1}(\phi) \equiv W^s_n(\phi) \subset W^s_n(\phi) \subset W^s_n(\phi) \subset \ldots
\]
By Property (P4), for \( \phi \neq \pm \pi/2 \), each \( W^s_n(\phi) \) is a real analytic curve, while \( W^s_n(\pm \pi/2) = I_{\pm \pi/2} \) for all \( n \geq 1 \). Hence the sets
\[
W^s(\phi) = \bigcup_{n=0}^{\infty} W^s_n(\phi).
\]
are real analytic curves for all \( \phi \in \mathbb{T} \). They are called the global stable manifolds of the points \( x = (\phi, 0) \in B \).\(^{24}\) Note that \( W^s(\pm \pi/2) = I_{\pm \pi/2} \); while \( W^s(0) = [\beta_0, \beta_1] \).

By construction, \( \mathcal{R}(W^s_n(\phi)) \subset W^s_n(4\phi) \), and, in fact, \( W^s_n(\phi) \) is the lift of \( W^s_n(4\phi) \) by \( \mathcal{R} \) that begins at \((\phi, 0) \in B \) (compare Lemma 3.2).

**Lemma 9.4.** The stable manifolds \( W^s(\phi) \) are strictly vertical curves.

**Proof.** The stable manifolds \( W^s(x) \) are tangent to the \( \text{Ker} \, \mathcal{D} \mathcal{R}(x) \). From representation \( R = f \circ Q \) in §3.2 we see that the \( \text{Ker} \, \mathcal{D} \mathcal{R}(x) = \text{Ker} \, \mathcal{D} Q(x) \) are orthogonal to \( B \). Hence the local stable manifolds \( W^s(x) \) go through the vertical algebraic cones \( K^v(x) \) (for \( \epsilon > 0 \) sufficiently small), so they are strictly vertical. Since the cone field \( K^v(x) \) is backward invariant (see Cor. 6.7), the global stable manifolds \( W^s(x) \) are strictly vertical as well. \( \square \)

9.4. Stable tongues. A tongue \( \Upsilon \) attached to a “tip” \( x \in T \) is a domain in \( C \) bounded by two proper vertical paths meeting only at \( x \). Note that \( \Upsilon \) meets \( B \) in an interval \( B_T \), called its bottom. A tongue is called stable if it is contained in \( W^s(B) \) and is foliated by proper stable manifolds \( W^s(\phi), (\phi, 0) \in B_T \) (terminating at \( x \)).

**Proposition 9.5.** There are two stable tongues \( \Upsilon(\alpha_\pm) \) attached to the indeterminacy points \( \alpha_\pm \) respectively. They are symmetric with respect to the collapsing intervals \( I_{\pm \pi/2} \) and have positive angles at the tip.

**Proof.** By the blow-up formula (3.4) points \( x \) approaching \( \alpha_{\pm \pi/2} \) at angle \( \omega \) from \( I_{\pm \pi/2} \) are mapped to the point \( \mathcal{G}(\omega) = (2\omega, \sin^2 \omega) \). This curve intersects the critical level \( \{t = t_c\} \) at two points, \( \mathcal{G}(\pm \omega_c) \). Moreover,
\[
\mathcal{G}[\omega_c, \omega_c] \subset C \times \{\beta_c, \beta'_c\} \subset W^s(B)
\]
Hence there is a region \( U \) under the arc \( \mathcal{G}[\omega_c, \omega_c] \) (comprised of two symmetric topological triangles) foliated by stable manifolds \( W^s(\phi) \) (see Figure 9.1). By Lemma 3.2, this region lifts by \( \mathcal{R} \) to two tongues \( \Upsilon'(\alpha_{\pm}) \) attached to \( \alpha_{\pm} \). Each \( \Upsilon'(\alpha_{\pm}) \) has angle \( 2\omega_c > 0 \) at the tip. The desired tongues \( \Upsilon(\alpha_{\pm}) \) are the maximal

\(^{24}\)This terminology is not completely standard, as usually the global stable manifold of \( x \) is defined as the set of all points that are forward asymptotic to the orb. In our situation, it would be \( U \cap R^{-1} W^s(4^n \phi) \), which is disconnected.
stable tongues containing $\Upsilon'(\alpha_{\pm})$. By $\pm \pi/2$-symmetry of the basin $W^n(B)$ (see Property (P1) in §3.3), they are symmetric with respect to the corresponding axes $I_{\pm}\pi/2$. □

The above tongues $\Upsilon_{\pm}$ will be called the primary stable tongues of $W^n(B)$.

For $n \in \mathbb{N}$, let

$$\mathcal{A}^n = \mathcal{R}^{-n}\{\alpha_{\pm}\} = \{(\phi_{n,k}, 1)\}_{k=0}^{2^n-1}, \text{ where } \phi_{n,k} = \frac{\pm \pi/2 + 2\pi k}{2^n}. $$

and let $\mathcal{A} = \cup \mathcal{A}_n$ be the pre-indeterminacy set.

**Proposition 9.6.** There is a family of disjoint stable tongues $\Upsilon_k(\alpha)$ attached to the points $\alpha \in \mathcal{A}$ such that

(i) $\mathcal{T}_0(\alpha_{\pm}) \equiv \Upsilon(\alpha_{\pm})$;

(ii) If $\alpha \neq \alpha_{\pm}$ then $\Upsilon_k(\alpha)$ is a regular lift of some $\Upsilon_j(\mathcal{R}(\alpha))$;

(iii) If $\alpha = \alpha_{\pm}$ but $k \neq 0$ then $\Upsilon^{n+1}_k(\alpha)$ is a singular lift of some $\Upsilon_j(\beta)$ with $\beta \in \mathcal{A}$;

(iv) The union $\cup \Upsilon_k(\alpha)$ is backwards invariant;

(v) The union of the bottoms of all the tongues is an open set of full Lebesgue measure in $B$.

**Proof.** Lemmas 9.4, 6.1, 3.2, and Corollary 6.7 imply that the lifts of stable tongues by $\mathcal{R}$ are stable tongues. So, taking all possible lifts of the principal tongues $\Upsilon(\alpha_{\pm})$ by the iterates of $\mathcal{R}$, we obtain an infinite family of stable tongues attached to points of $\mathcal{A}$.

Since the stable manifolds are disjoint, the stable tongues with different tips are disjoint. If one of these tongues overlaps with a principal tongue $\Upsilon(\alpha_{\pm})$ then it must be contained in it, by maximality of the latter. It follows that any two tongues in the family are either disjoint or nested. Keeping only the maximal tongues, we obtain the desired family of tongues.
All the properties of this family are straightforward except the last one. This one follows from ergodicity of the map $z \mapsto z^4$ with respect to the Lebesgue measure on $T$, which implies that $\bigcup R^{-n}(B_{T^\pm})$ has full measure. \hfill \square

**Proposition 9.7.** The family of stable tongues $T_k(\alpha_\pm)$ is contained in the central tongue $\Lambda_\pm$, and their bottoms form an open set of full Lebesgue measure in the bottom of $\Lambda_\pm$ ($=(\pi/4,3\pi/4)$). Moreover, each of these tongues has positive angle at its tip. The same property is valid for $\alpha_-$.\hfill \square

**Proof.** Let us say that a topological rectangle $\Pi \subset C_-$ is a **singular stable rectangle** if it is bounded by an interval on $B$, an arc of $G$, and two proper vertical paths in $C_-$, and is foliated by stable leaves.\footnote{We allow one of the vertical sides to degenerate to $\beta_0$, making $\Pi$ degenerate to a triangle.} For instance, the intersection of any stable tongue $T_k(\alpha_\pm)$ with $C_-$ is singular stable rectangle (by Lemmas 9.4 and 6.1).

Let $\Pi_k$ be the family of maximal singular stable rectangles. Proposition 9.6 (v) implies that their bottoms have full measure in $B$.

Any singular stable rectangle lifts to a stable tongue attached to the indeterminacy points $\alpha_\pm$ with positive angle at the tip (equal to $|\omega_1 - \omega_2|$ where $G(\omega_i)$ are the upper vertices of $\Pi$). Lifting the rectangles $\Pi_k$, we obtain the desired family of tongues. \hfill \square

9.5. **Long hairs growing from $T$.** Let us recall dynamics on the invariant interval $I_0$ (see §3.1). Let

$$I_0^+ = \{ (\phi, t) \in I_0 : \ t > t_c \}, \quad I_0^\delta = \{ (\phi, t) \in I_0 : \ t \geq t_c + \delta \}.$$  

The interval $I_0^+$ is the stable manifold of the high temperature fixed point $\beta_1 \in T$. In this section it will be convenient to orient $I_0^+$ so that it begins at $\beta_1$.

We say that a sequence of curves $\gamma_k$ **stretch along $I_0^+$** if for any $\delta > 0$ there is $k_0$ such that the curves $\gamma_k, k \geq k_0$, contain arcs that can be represented as graphs $\phi = \gamma_k(t)$ over $I_0^\delta$ such that $\gamma_k \to 0$ in $C^1(I_0^+)$.

Let us consider a sequence of preimages $\beta_k \in T$ of $\beta_1$ converging to $\beta_1$, say $\beta_k = (2\pi/2k^{-1}, 1)$. Let $\gamma_k$ stand for the lift of $I_0^+$ by $R^k$ that begins at $\beta_k$.

**Lemma 9.8.** The curves $\gamma_k$ are pairwise disjoint, and the orbits of points $x \in \bigcup \gamma_k$ converge to $\beta$. Moreover, the curves $\gamma_k$ stretch along $I_0^+$.

**Proof.** The first assertion is obvious. The last one follows from the Dynamical $\lambda$-Lemma (see [PM, pp. 80-85]) applied near the hyperbolic fixed point $\beta_1$. \hfill \square

**Proposition 9.9.** There are infinitely many tongues $T_k(\alpha_\pm)$. Each of them sticks at a positive angle out of the top $T$.

**Proof.** Let $\gamma'_k$ be the curves $\gamma_k$ translated horizontally by $\pi$. They stretch along the interval $I_0^+ = \{ (\phi, t) \in I_0 : \ t > t_c \}$ and hence (for $k$ sufficiently big) intersect the singular curve $G$ transversally near the top.

By the symmetry $R(\phi + \pi) = R(\phi)$ (see Property (P1)), the orbits of points $x \in \bigcup \gamma_k$ converge to $\beta$. So, $\bigcup \gamma'_k$ is disjoint from the basin $W^u(B)$, and hence the singular stable rectangles from the proof of Proposition 9.7 can meet $G$ only in between the curves.
Figure 9.2. The primary stable tongues.

Since the tips of the stable tongues $\Upsilon(\alpha)$ are dense in $T$, there is a tongue $\Upsilon(\alpha_k)$ “squeezed” in between any pair of curves $\gamma_k'$ and $\gamma_{k+1}'$. Then the corresponding rectangles $\Upsilon(\alpha_k) \cap C_-$ are contained in disjoint (for $k$ big enough) maximal rectangle $\Pi_k$. The latter lift to disjoint stable tongues $\Upsilon_k(\alpha_{\pm})$. This proves the first assertion.

The second one follows as well since any singular stable rectangle $\Pi$ is separated from $I_{\pi}$ by some curve $\gamma_k'$, hence the corresponding tongue (the singular lift of $\Pi$) meets the top non-tangentially. □

Corollary 9.10. The stable tongues $\Upsilon_k(\alpha_{\pm})$ have angles $0 < \omega_k(\alpha_{\pm}) < \pi$ at their tips. All other stable tongues $\Upsilon_k(\alpha)$, $\alpha \neq \alpha_{\pm}$, have cusps at their tips.

Proof. The angles $\omega_k(\alpha_{\pm})$ are positive by Propositions 9.5 and 9.9. Since $\sum \omega_k(\alpha_{\pm}) = \sum \omega_k(\alpha_-) \leq \pi$, each of the angles is also strictly smaller than $\pi$.

By Property (ii) of Proposition 9.6, the other stable tongues $\Upsilon_k(\alpha)$ are regular pullbacks of the $\Upsilon_k(\alpha_{\pm})$. Since $R$ is transversely super-attracting at $T$ (away from $\alpha_{\pm}$) and expanding along $T$, these pullbacks have cusps at the tips. □

9.6. Regularity.

Proposition 9.11. $F^s(B)$ is a $C^\infty$ foliation of $W^s(B)$.

Since the leaves of $F^s(B)$ are integral curves of the central line field $L^c$, it suffices to prove the following proposition.

Proposition 9.12. The sequence $B_n(x) := \frac{1}{4^n} DR^n(x)$ converges uniformly on compact subsets of $W^s(B)$ at super-exponential rate to a $C^\infty$ matrix-valued function $B(x)$. Moreover, $L^c(x) = \ker B(x)$.

Proof of Proposition 9.12. It suffices to prove the statement in any neighborhood of $B$, since one can use the invariance

\[
4B_n(x) = B_{n-1}(Rx)DR(x) \quad \text{and} \quad 4B(x) = B(Rx)DR(x),
\]

to extend the result to any compact subset of $W^s(B)$. For example, $\ker B(x) = \mathcal{R}^* \ker B(Rx)$ follows automatically from (9.3) at the regular points of $\mathcal{R}$ and is a simple check near the critical points $I_{\pm\pi/2}$.

For $x \in C_*$ we have

\[
t_n \leq Cq^{2^n}
\]

26 This is a reason why the tongues do not appear to reach $T$ on Figure 1.2.
with $C > 1$ and $0 < q < 1$. It is noteworthy that $C \equiv C(\epsilon)$ and $q \equiv q(\epsilon)$ can be chosen uniformly on the region $C_\epsilon^* := \{ x \in C : t(x) < t_\epsilon - \epsilon \}$ for any $\epsilon > 0$.

Note that $A(x) := \frac{1}{q}D\mathcal{R}(x)$ is real-analytic and, by (B.6), it satisfies

$$A(\phi, 0) = A_0 := \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$ 

It follows from (9.4) that

$$|A(\mathcal{R}^n x) - A_0| < C_0 q^n$$

for any $x \in C^*_\epsilon$.

By the chain rule

$$D\mathcal{B}_n(x) = A(\mathcal{R}^{-1} x)A(\mathcal{R}^{-1} x) \cdots A(x).$$

Moreover, Equation (9.5) is sufficient for $B_n(x)$ to converge uniformly (and super-exponentially fast) to some continuous $B(x)$ on $C^*_\epsilon$ for any $\epsilon$. It satisfies $B(\phi, 0) = A_0$ and also $4B(x) = B(\mathcal{R}x)D\mathcal{R}(x)$.

Since $B$ is superattracting, there is some forward invariant neighborhood $\mathcal{N}$ of $B$ so that for any $x \in \mathcal{N}$, any $v \in \mathcal{L}(x)$ has its length contracted under $D\mathcal{R}$ by a definite factor, thus satisfying $v \in \ker B(x)$. Moreover, since $B(\phi, 0) = A_0$ we can trim this neighborhood, if necessary, so that rank $B(x) = 1$ and thus $\mathcal{L}(x) = \ker B(x)$ for all $x \in \mathcal{N}$.

We now show that $B(x)$ is $C^\infty$ in $C^*_\epsilon$. The proof depends on the superattracting nature of $B$. Let $\mathcal{R} = (\mathcal{R}_1, \mathcal{R}_2)$. Then, $\mathcal{R}_2$ vanishes quadratically in $t$ when $t = 0$, giving that for any multi-index $\beta$ there is some $M_\beta$ such that

$$|\partial_\beta \mathcal{R}_2(\phi, t)| \leq \begin{cases} \frac{t^2}{C^2} M_\beta & \text{if } \beta_2 = 0 \\ \frac{t}{C} M_\beta & \text{if } \beta_2 = 1 \\ M_\beta & \text{if } \beta_2 \geq 2 \end{cases}$$

for all $(\phi, t) \in C^*_\epsilon$. Furthermore, since $A(x) - A_0$ vanishes at $t = 0$, we have that

$$\|\partial_\beta A\| < C_3 t \text{ if } \beta_2 = 0.$$ 

We'll first observe that $B(x)$ is $C^1$. It is a consequence of the following estimates

$$\|D\mathcal{R}^n(x)\| \leq \lambda^n,$$ 

$$\|\partial_x t_n\| \leq \mu^n q^{2^n},$$ 

$$\|\partial_x A(\mathcal{R}^n x)\| \leq C_1 \nu^n q^{2^n}.$$ 

for appropriate $\lambda, \mu, \nu$, and $C_1$.

The first follows a bound $\|D\mathcal{R}(x)\| \leq \lambda$ on $C^*_\epsilon$ and the chain rule. Meanwhile (9.9) follows from induction on $n$, since the chain rule and (9.6) give

$$\partial_x t_n = \partial_x \mathcal{R}_2(\phi_{n-1}, t_{n-1}) \partial_x \phi_{n-1} + \partial_t \mathcal{R}_2(\phi_{n-1}, t_{n-1}) \partial_t t_{n-1} \leq \frac{t_{n-1}^2}{C^2} M_\phi \cdot \partial_x \phi_{n-1} + \frac{t_{n-1}}{C} M_1 \cdot \partial_x t_{n-1}.$$ 

Equation (9.10) follows from similar use of the chain rule, together with (9.7), (9.9), and (9.8).

Then (9.10) is sufficient for the series

$$\partial_x B(x) = \partial_x A(x)A(\mathcal{R}x)A(\mathcal{R}^2 x) \cdots + A(x)\partial_x A(\mathcal{R}x)A(\mathcal{R}^2 x) \cdots + \cdots$$
to converge uniformly on $C_\epsilon^*$ for any $\epsilon > 0$.

To prove the convergence of higher derivatives of $B(x)$ we will use

**Lemma 9.13.** For $x \in C_\epsilon^*$ and any multi-index $\alpha = (\alpha_1, \alpha_2) \neq 0$ we have

\[(9.13) \quad \|\partial_\alpha R^n(x)\| < \lambda^n_\alpha, \]
\[(9.14) \quad |\partial_\alpha t_n| < \mu^n_\alpha q^n, \quad \text{and} \]
\[(9.15) \quad \|\partial_\alpha A(R^n x)\| < C^n_\alpha \nu^n_\alpha q^n,
\]
for suitable $\lambda_\alpha, \mu_\alpha, \nu_\alpha > 1$ and $C_\alpha > 0$.

**Proof.** The proof is similar to that for (9.8-9.10) except that in place of the chain rule we will use the the Faà di Bruno formula [CS] to estimate the higher partial derivatives of a composition.

If

\[h(x_1, \ldots, x_d) = f(g^{(1)}(x_1, \ldots, x_d), \ldots, g^{(m)}(x_1, \ldots, x_d))\]

and $|\alpha| := \sum \alpha_i$, it gives:

\[(9.16) \quad \partial_\alpha h = \sum_{1 \leq |\beta| \leq |\alpha|} \partial_\beta f \sum_{s=1}^{|\alpha|} \sum_{p_s(\alpha, \beta)} \alpha! \prod_{j=1}^s \frac{(\partial_{l_j} g)^{k_j}}{k_j!},\]

Each $\beta$ and $k_j$ is a $n$-dimensional multi-index and each $l_j$ is a $d$-dimensional multi-index. The final sum is taken over the set

\[p_s(\alpha, \beta) = \{(k_1, \ldots, k_s; l_1, \ldots, l_s) : |k_i| > 0, 0 < l_1 \prec \cdots \prec l_s, \sum_{i=1}^s k_i = \beta \text{ and } \sum_{i=1}^s |k_i| l_i = \alpha\}.\]

Here, $\prec$ denotes a linear order on the multi-indices (its details will not be important for us), $\eta! := \prod \eta_i!$, and for a vector $z$ we have $z^n = \prod z_i^n$.

We will not need the precise combinatorial details of this formula. For example, (9.13) follows directly from the existence of a polynomial expression for $\partial_\alpha h$ in the partial derivatives of $f$ and $g$.

Suppose that both $f$ and $g$ are functions of two variables. Then, all that we will need to prove (9.14) and (9.15) is that the Faà di Bruno formula gives an expression of the form

\[(9.17) \quad \partial_\alpha h = \sum_i K_i \partial_\beta_i f \prod_{j=1}^{\beta^i_1} \partial_{\gamma_{i,j}} g^{(1)} \prod_{j=1}^{\beta^i_2} \partial_{\eta_{i,j}} g^{(2)},\]

having two additional properties:

1. $1 \leq |\beta_i, \gamma_{i,j}, \eta_{i,j}| \leq |\alpha|$ for every $i, j$ and, if either $\gamma_{i,j} = \alpha$ or $\eta_{i,j} = \alpha$, then $|\beta_i| = 1$; and

2. $K_i \geq 1$ for every $i$.

Here, each $\beta_i = (\beta^i_1, \beta^i_2)$.

The proof of (9.14) is done by an inductive use (9.17) similar to the usage of the chain rule for the first derivatives (9.11). It is the key step, so we’ll prove it here and omit a proof of (9.15), which is simpler.
We already have (9.14) when $|\alpha| = 1$. Therefore, can suppose that it holds for all $\beta$ satisfying $|\beta| < |\alpha|$ in order to prove it for $\alpha$. Equation (9.17) gives

$$
(9.18) \quad \partial_{\alpha} t_n = \sum_i K_i \partial_{\beta_i} R_2(x_{n-1}) \prod_{j=1}^{\beta_i^1} \partial_{\gamma_{i,j}} \phi_{n-1} \prod_{j=1}^{\beta_i^2} \partial_{\eta_{i,j}} t_{n-1}.
$$

Let $\mu_\alpha := \max(N_\alpha, P_\alpha)$, where

$$
N_\alpha := \frac{1}{q^2} \sum_i K_i M_{\beta_i}
$$

and $P_\alpha$ is the maximum of

$$
\prod_{j=1}^{\beta_i^1} \lambda_{\gamma_{i,j}} \prod_{j=1}^{\beta_i^2} \mu_{\eta_{i,j}}
$$

taken over all $i$ in (9.18).

Equation (9.14) follows for $n = 1$, since $\mu_\alpha \geq N_\alpha \geq \frac{1}{q^2} M_\alpha \geq \frac{1}{q^2} |\partial_1 t_1|$.

We now suppose that (9.14) is true for the $(n - 1)$-th iterate in order to prove it for the $n$-th iterate. By the definition of $\mu_\alpha$, it suffices to show that each term in (9.18) has absolute value bounded by

$$
(9.19) \quad q^{2n} K_i M_{\beta_i} \left( \prod_{j=1}^{\beta_i^1} \lambda_{\gamma_{i,j}} \prod_{j=1}^{\beta_i^2} \mu_{\eta_{i,j}} \right)^{n-1}.
$$

If $\beta_i^2 \geq 2$, then the factor of $q^{2n}$ results from at least two factors of $|\partial_{\eta_{i,j}} t_{n-1}|$ in the $i$-th term from (9.18) and the induction hypothesis. Otherwise, sufficient extra factors of $q^{2n-1}$ come from from $t_{n-1} \leq C q^{2n-1}$ and (9.6). \hfill \Box

Using a generalization of the product rule, we have

$$
(9.20) \quad \partial_\alpha B(x) = \sum_{\alpha = \alpha_0 + \alpha_1 + \cdots} \frac{\alpha!}{\alpha_0!\alpha_1!\alpha_2!} \partial_{\alpha_0} A(x) \cdot \partial_{\alpha_1} A(R x) \cdot \partial_{\alpha_2} A(R^2 x) \cdots
$$

where the sum is taken over all partitions of $\alpha$ into a sum $\alpha_0 + \alpha_1 + \cdots$. We apply (9.15) to each $|\alpha_i| \leq |\alpha|$ and take appropriate maxima to find

$$
|\partial_{\alpha_n} A(R^n x)| \leq D_1 \nu^n \tilde{q}^{2n} \leq D_2
$$

for each $n$ and suitable $\nu > 1, D_1 > 0$, and $D_2 > 0$.

There are no more than $n^{|\alpha|}$ partitions $\alpha = \alpha_0 + \alpha_1 + \cdots$ for which $n$ is the maximal index with $|\alpha_i| > 0$. Each such term in the sum (9.20) can be bounded by $K \nu^n \tilde{q}^{2n}$, since there are at most $|\alpha|$ terms in the product for which $\alpha_i \neq 0$, each of which is bounded by $D_2$, and the last one is bounded by $D_1 \nu^n \tilde{q}^{2n}$. Thus, we bound the sum (9.20) by

$$
\sum_n n^{\alpha} K \nu^n \tilde{q}^{2n},
$$

which is convergent.

Thus the series (9.20) for $\partial_\alpha B(x)$ converges uniformly on $C_\epsilon$ for any $\epsilon > 0$. Since the multi-index $\alpha$ was arbitrary, we conclude that $B(x)$ is $C^\infty$ on $C_\epsilon$. \hfill \Box
9.7. “Böttcher coordinate” on $W^s(B)$ and convergence of foliations. Since the map $R : C \to C$ has degree 4 in the first homology of $C$, the normalized pullback

$$\phi_1 : C_1 \to T, \quad \phi_1 = \frac{1}{4} \phi \circ R : C_1 \to T$$

is a well defined map of degree 1. Iterating the pullback, we obtain a sequence of degree 1 maps

$$\phi_n : C_1 \to T, \quad \phi_n = \frac{1}{4^n} \phi \circ R^n : C_1 \to T.$$ 

By Proposition 9.6,

$$d\phi_n(x) = d\phi(R^n x) \cdot B_n(x) \to (1, 0) \cdot B(x) : = \omega(x), \quad x \in B,$$

where $\omega$ is a closed $C^\infty$-smooth 1-form on $W^s(B)$ with period 1. Hence $\omega = d\Phi$ where $\Phi : W(B) \to T$ is a $C^\infty$ map of degree 1. Moreover,

$$(9.21) \quad \Phi|_B \equiv \phi, \quad \Phi(R x) = 4\Phi(x).$$

Since $d\Phi$ vanishes on the stable leaves $W^s(x)$ ($x \in B$) and does not vanish transversally, it is a defining function for the stable foliation.

The function $\Phi$ plays the role of the Böttcher coordinate on the basin of the bottom. Instead of the angular coordinate $\phi$, we can do the same construction with a more general function:

**Lemma 9.14.** Let $\psi : C_1 \to T$ be a $C^\infty$-map of degree $l$ tangent to $l\phi$ at the bottom (i.e., $\psi(\phi, t) = l\phi + o(t)$ as $t \to 0$). Then

$$\psi_n := \frac{1}{l \cdot 4^n} \psi(R^n x) \to \Phi(x) \quad \text{super-exponentially fast as } n \to \infty,$$

in the $C^1$-topology on compact subsets of $W^s(B)$.

**Proof.** The same reason as above shows that $d\psi_n \to d\Phi$ super-exponentially fast in the $C^1$-topology on compact subsets of $W^s(B)$. The assertion follows, since the $\psi_n$ agree with $\phi$ on $B$. $\Box$

If $\psi$ is a defining function for some foliation $\mathcal{F}$ on $W^s(B)$, then the $\psi_n$ are defining functions for the pullbacks $(R^n)^*(\mathcal{F})$, and Lemma 9.14 gives a strong sense in which these pullbacks converge to the stable foliation of the bottom $\mathcal{F}^s(B)$.

Let us finally mention that the Böttcher coordinate $\Phi$ can be extended continuously to a degree 1 map $\tilde{\Phi} : C_1 \to T$ satisfying Böttcher functional equation (9.21), see Remark 12.1 below.

10. High temperature dynamics: basin of the top of the cylinder

Property (P5) from §3.3 states that the top $T$ of the cylinder $C$ is non-uniformly superattracting. In this section we will prove that there is set of positive measure attracted to $T$,

$$W^s(T) = \{ x \in C : R^n x \to T \},$$

that supports a “stable bouquet” $\mathcal{F}^s(T)$ consisting of curves emanating from almost all points of $T$.

Near the top, we will make use of the local coordinate $\tau$, and near the indeterminacy points – of the local coordinates $(\tau, \epsilon)$, see (P5). We say that “$x$ is $\tau$-below $y$” if $\tau(x) < \tau(y)$ (so, $x$ is, in fact, above $y$ on the cylinder $C$).
Recall the neighborhoods $\mathcal{V}' \equiv \mathcal{V}'_{\tau, \eta}$ of $T \setminus \{ \alpha_{\pm} \}$ obtained by removing the parabolic regions $P_{\pm, \eta}$ from the $V_{\tau}$ neighborhood of the top (see §6.2.) Let $q \in (0, 1)$. By property (P5), if $\eta$ and $\tilde{\tau}$ are sufficiently small then

(10.1) $\tau(Rx) < q \tau(x)$ \quad $\forall$ $x \in \mathcal{V}'$.

Let $W^{s}_{\eta, \pm}(T)$ be the set of points whose orbits converge to $T$ while remaining in $\mathcal{V}'_{\tau, \pm}$ and let $W^{s}_{\eta, \pm}(T)$ be the set of points whose orbits eventually land in $\mathcal{V}'_{\tau, \eta}$ for some $\tilde{\tau}$ and stay there (note that this property is independent of $\tilde{\tau}$). Then, points of $W^{s}_{\eta}(T)$ are attracted to $T$ with exponential rate $O(q^n)$. We will show below that this set supports a “stable bouquet” $F^{s}_{\eta}(T)$ consisting of curves emanating from almost all points of $T$ and that it has positive two-dimensional Lebesgue measure.

10.1. Vertical bouquet $F^{s}(T)$. A bouquet of curves in $\mathcal{C}$ is a family of curves that are disjoint on $\mathcal{C}_1$ (which may or may not be a lamination). The curves comprising the bouquet are called its leaves.

In the following proposition, horizontal and vertical curves $\gamma$ are understood in the sense of the cone fields $K^h$ and $K^v$. Vertical curves are oriented by the local coordinate $\tau$. Note that for sufficiently small $\eta$, the boundary of $\mathcal{V}'$ is horizontal because the tangent lines to the parabolas $\gamma^v_{\eta}$ have slope $2\eta$ which can be made less than $\epsilon/3$.

**Proposition 10.1.** For any sufficiently small $\eta > 0$, the basin $W^{s}_{\eta}(T)$ supports an invariant bouquet $F^{s}(T) \equiv F^{s}_{\eta}(T)$ by smooth vertical paths landing transversely at almost all points of $T$.

**Proof.** Let $q \in (0, 1)$. A vertical curve $\gamma$ is called semi-proper if it begins on $T$. If additionally, $\gamma$ lands on the $\tau$-upper boundary of $\mathcal{V}'$, it is called proper.

Let

$$\mathcal{V}'_n = \{ x : R^k x \in \mathcal{V}', k = 0, \ldots, n - 1 \}.$$ 

Let $\gamma^0 = \gamma^0_n \subset \mathcal{V}'$ be the proper genuinely vertical interval containing $x \in \mathcal{V}' \equiv \mathcal{V}'_{\tau, \eta}$. For each $n > 0$ and $x \in \mathcal{V}'_n$, we will inductively construct a semi-proper vertical curve $\gamma^n = \gamma^n_x \subset \mathcal{V}'_n$ containing $x \in \mathcal{V}'_n$. Assume we have already constructed curves $\gamma^y_{n-1}$ for all $y \in \mathcal{V}'_{n-1}$. Then for $x \in \mathcal{V}'_n$, we define $\gamma^n_x$ as the regular lift of $\gamma^n_{x_{\tau}}$ truncated (if needed) by the $\tau$-upper boundary of $\mathcal{V}'$. Since the cone field $K^v$ is backward invariant, we obtain a semi-proper vertical curve. Since the boundary of $\mathcal{V}'$ is horizontal and $x \in \mathcal{V}'$, the whole curve $\gamma^n_x$ is contained in $\mathcal{V}'$. Since $\gamma^n_{x_{\tau}} \subset \mathcal{V}'_{n-1}$, we conclude that $\gamma^n_x \subset \mathcal{V}'_n$.

Let $x \in W^{s}_{\eta, \pm} = \bigcap \mathcal{V}'_n$, so that the curves $\gamma^n_y$ exist for all $n \in \mathbb{N}$. Since each of them contains $x$, they all have a definite height $\tau_0 \geq \tau(x)$. Since $R$ is horizontally expanding, the curves $\gamma^n_y$ exponentially converge in the uniform topology to a curve $\gamma_x$ containing $x$ and of height $\geq \tau_0$. Moreover, being vertical, the curves $\gamma^n_x$ are uniformly Lipschitz, so $\gamma_x$ is Lipschitz as well.

The results of §7 gives that the intersections $\cap DR^{-n}(K^v(R^n x))$ converge geometrically to the central line field $L^c(x)$. Thus, $\gamma_x$ is tangent to $L^c(x)$ at $x$. Similarly, at any $y \in \gamma_x$ we have that $\gamma_x$ is tangent to $L^c(y)$. Since the $L^c$ is a continuous line field, the entire curve $\gamma_x$ is $C^1$.

It lands at $T$ transversely since the vertical cone field $K^v$ is non-degenerate on $T \setminus \{ \alpha_{\pm} \}$. (Note that the curves $\gamma_x$ do not land at $\alpha_{\pm}$ since they are vertical while $\partial \mathcal{V}'$ is horizontal.)
So, the basin $\mathcal{W}_{\eta, \bar{T}}^n$ supports an invariant bouquet by smooth vertical paths landing transversely at $\mathcal{T}$. Pulling it back by the dynamics, we obtain a similar bouquet supported on the whole basin $\mathcal{W}_{\eta}^n$. To complete the proof we need to show that the leaves of this bouquet land at almost all points of $\mathcal{T}$.

Let $\epsilon_n(\phi) = c(\mathcal{R}^n(\phi))$ (where $\phi$ is considered to be a point on $\mathcal{T}$). Since the doubling map $\mathcal{R}: \phi \mapsto 2\phi$ preserves the Lebesgue measure on $\mathcal{T}$, the Borel-Cantelli Lemma implies that for a.e. $\phi \in \mathcal{T}$, eventually we have: $\epsilon_n(\phi) > q^{n/4}$. Hence for a.e. $\phi \in \mathcal{T}$, there exists $c = c(x) > 0$ such that

$$
(10.2) \quad \epsilon_n(\phi) > cq^{n/4}, \quad n \in \mathbb{N}.
$$

Let $h(\phi) = \min\{\tilde{r}, \eta \epsilon^2/2\}$, so that any vertical curve $\gamma$ based at $\phi \in \mathcal{T}$ of $\tau$-height $\leq h(\phi)$ is necessarily contained in $\mathcal{V}'$. (To check it, note that a vertical curve that begins at $\epsilon_0$-distance from $\alpha_+$ goes $\tau$-below the parabola $\tau = (\epsilon_0^2 - \epsilon^2)/4$, and hence reaches the boundary parabola $Y_n = \{\tau = \eta \epsilon^2\}$ at least at $\tau$-height $\eta \epsilon^2/(1 + 4\eta)$.)

Let us now slightly modify the above construction of semi-proper vertical curves. Let $\gamma_0^n \subset \mathcal{V}'$ be the proper vertical (straight) interval based at $\phi \in \mathcal{T}$. For each $n > 0$ we will inductively construct a family of semi-proper vertical curves $\gamma^n_0 \subset \mathcal{V}'$ based at $\phi \in \mathcal{T}$. Assume we have already constructed curves $\gamma^n_{\phi}$. Then we define $\gamma^n_{\phi}$ as the regular lift of $\gamma^n_{2\phi}$ truncated (if needed) by the $\tau$-upper boundary of $\mathcal{V}'$. Since the cone field $K^n$ is backward invariant, we obtain a family of semi-proper vertical curves.

We will now show that if $\phi$ satisfies (10.2) then the curves $\gamma^n = \gamma^n_{\phi}$ have a definite height (depending on $\phi$ but independent of $n$). Indeed, by construction, one of the curves $\mathcal{R}^k(\gamma^n)$, $k = 0, 1, \ldots, n$, is proper. But the height of $\mathcal{R}^n(\gamma^n)$ is bounded by $q^n\tilde{T}$ which is eventually smaller than

$$
\frac{\eta}{2} \epsilon^2 q^n/2 \leq \min\{\frac{\eta}{2} \epsilon^2, \tilde{T}\} = h(\phi_n).
$$

Hence there is $k_0 = k_0(\phi)$ (independent of $n$) such that all the curves $\mathcal{R}^k_\phi \gamma^n$ are not proper for $k > k_0$. It follows that one of the curves $\mathcal{R}^k_\phi \gamma^n$, $k = 0, 1, \ldots, k_0$, is proper, and hence, it has a definite height. Then the same is true for the curve $\gamma^n_{\phi}$. This completes the proof.\hfill \Box

10.2. Positive measure of $\mathcal{W}^n(\mathcal{T})$. Let

$$
\mathcal{W}_{\eta, \bar{T}}^n(\mathcal{T}) := \{x \in \mathcal{W}_{\eta}^n(\mathcal{T}) : \text{the curve } \gamma_x \in \mathcal{F}_{\eta} \text{ containing } x \text{ extends beyond } x\}.
$$

It is a completely invariant subset of $\mathcal{W}_{\eta}^n(\mathcal{T})$ consisting of points $x \in \mathcal{W}_{\eta}^n$ whose orbits $\mathcal{R}^n x$ converge to $\mathcal{T}$ within the interiors of the corresponding leaves $\gamma_{\mathcal{R}^n x}$.

Let

$$
\pi : \mathcal{C} \to \mathcal{B} = \mathcal{T}, \quad (\phi, t) \mapsto \phi
$$

be the natural projection onto the bottom of the cylinder.

Given a horizontal curve $\xi$, let $dl^h \equiv dl^h_\xi = \pi^*(d\phi)$ stand for the horizontal length on it, i.e., the pullback of the standard Lebesgue measure on $\mathcal{T}$ to $\xi$ under $\pi$. So, if $\xi$ projects injectively onto the horizontal axis (or equivalently, if $l^h(\xi) \leq 2\pi n$) then $l^h(X) = |\pi(X)|$ for any measurable set $X \subset \xi$ (where $|Y|$ stands for the Lebesgue measure of $Y \subset \mathcal{T}$). In general,

$$
(10.3) \quad l^h(X) = \int |(\pi|X)^{-1}(\phi)| d\phi \leq \deg(\pi|X)|\pi(X)|,
$$

where $\deg(\pi|X) = \max_{\phi \in \mathcal{T}} |(\pi|X)^{-1}(\phi)|$. 

By Theorem 8.1, \( R \) expands the horizontal length: there exists \( \lambda > 1 \) and \( c > 0 \) such that for any horizontal curve \( \xi \subset \mathcal{V}' \) and any measurable set \( X \subset \xi \), we have:

\[
(10.4) \quad l^h(R^n X) \geq c\lambda^n l^h(X).
\]

**Remark 10.1.** In fact, \( \lambda = 2 \) but we will keep notation “\( \lambda \)” to distinguish it from the combinatorial appearance of “\( 2 \)”. Note also that in region \( \mathcal{V}' \) (which we are concerned with in this section) expanding property (10.4) can be easily derived from Lemma B.4.

**Lemma 10.2.** For any \( \eta \in (0, 1/2) \) and \( \delta > 0 \), there exists a threshold \( \bar{\tau} > 0 \) with the following property. Let \( \xi \) be a horizontal curve in the strip \( \mathcal{V}_\bar{\tau} \) with \( l^h(\xi) < 2\pi \).

Then all points of \( \xi \), except for a set of horizontal length \( < \delta \), belong to \( \mathcal{W}^{n, \alpha}(T) \).

**Proof of Lemma 10.2.** Making \( \eta \) and \( \bar{\tau} \) sufficiently small, we can assume if \( \gamma \subset \mathcal{V}^\prime_{2\bar{\tau}, \eta} \) is any vertical curve then the vertical length\(^{27} \) of \( R\gamma \) is at least a factor of \( q < 1/4 \) smaller than the vertical length of \( \gamma \). This slightly stronger condition than (10.1) can be obtained using (B.7) and (B.8).

Let

\[
(10.5) \quad \xi_n = \left\{ x \in \xi : \left| e(R^k x) \right| \geq 2 \sqrt{\bar{\tau}/\eta} \cdot 2^{-k} \text{ for } 0 \leq k \leq n - 1 \text{ and } \left| e(R^n x) \right| < 2 \sqrt{\bar{\tau}/\eta} \cdot 2^{-n} \right\},
\]

and let \( X_n = R^n(\xi_n) \). Note that the sets \( \xi_n \) are pairwise disjoint.

Using (10.1), one can inductively show that \( \xi \setminus \cup \xi_n \subset \mathcal{W}^\prime_0(T) \). Let us now estimate \( l^h(\cup \xi_n) \). By construction

\[
|\pi(X_n)| \leq 8\sqrt{\bar{\tau}/\eta} 2^{-n}.
\]

Making use of (10.3), we obtain:

\[
l^h(X_n) \leq 8\sqrt{\bar{\tau}/\eta} \deg(\pi|X_n) 2^{-n}.
\]

Together with (10.4), this implies

\[
l^h(\xi_n) \leq 8\sqrt{\bar{\tau}/\eta} \deg(\pi|X_n) 2^{-n} c^{-1} \lambda^{-n}.
\]

We will show that

\[
(10.6) \quad \deg(\pi|X_n) \leq 2^n.
\]

Indeed, in this case \( l^h(\xi_n(x)) \leq 8\sqrt{\bar{\tau}/\eta} c^{-1} \lambda^{-n} \), hence

\[
(10.7) \quad l^h(\cup \xi_n) = \sum_{n=0}^{\infty} l^h(\xi_n(x)) \leq 8\sqrt{\bar{\tau}/\eta} \frac{\lambda}{c(\lambda - 1)},
\]

which can be made arbitrarily small if \( \bar{\tau} \) is selected small enough.

Let us prove (10.6). For \( x \in \xi_n \), let \( x_k = R^k x \), and let \( \phi = \pi(x_n) \). Let \( \gamma_n \equiv \gamma_n(x) \subset I_\phi \) be the genuine vertical interval connecting \( x_n \) to \( T \), and let \( \gamma_k \equiv \gamma_k(x) \) be its lifts that connect \( x_k \) to \( T \). Since \( x_k \in \mathcal{V}' \) for \( k < n \), and the region \( \mathcal{V}' \) lies above the tongues \( \Lambda_{\pm} \) (defined by Property P6 and Figure 3.3), the lifts \( \gamma_k \) are regular, i.e., they lie in the regular lifts \( I_k \) of the interval \( I_\phi \) (where the lift \( I_k \) terminates at the point \( (\phi + 2\pi j)/2^k \) of \( T \), \( j = 0, 1, \ldots, 2^k - 1 \)). But each lift \( I_k \) is vertical since the vertical cone field \( K^V \) is backward invariant. Hence each

\(^{27}\)In general, \( R\gamma \) need not be vertical. In all cases, the vertical length of \( R\gamma \) can be considered as the total length its projection onto the vertical interval \( I_0 \).
that \( I'^i \) crosses the horizontal curve \( \xi \) at most once. Hence, given \( \phi = \pi(x_n) \), there are at most \( 2^n \) points \( x \in \xi_n \) such that \( \pi(x_n) = \phi \), and (10.6) follows.

It remains to prove that \( \xi \setminus \cup \xi_n \) is actually a subset of \( \mathcal{W}^\omega_{\eta,\tau}(T) \). We will show that the leaf \( \gamma_x \in \mathcal{F}^\omega_{\eta}(T) \) through any \( x \in \xi \setminus \cup \xi_n \) extends beyond \( x \) by a definite amount. It suffices to verify that this holds for each of the curves \( \gamma^n_x \) used in the proof of Proposition 10.1 to construct \( \gamma_x \).

There is a constant \( K > 0 \) so that if \( \tau(x) \leq \tilde{\tau} \) and

\[
|\varepsilon(x)| \geq 2\sqrt{\frac{\tau(x)}{\eta}},
\]

then any proper vertical curve \( \gamma \) in \( \mathcal{W}^\omega_{2\tilde{\tau},\eta} \) containing \( x \) extends beyond \( x \) by at least \( K|\varepsilon(x)|^2 \).

To see it, let \( \tilde{x} \) be the point where \( \gamma \) reaches the \( \tau \)-upper boundary of \( \mathcal{W}^\omega_{2\tilde{\tau},\eta} \). If \( \tau(\tilde{x}) = 2\tilde{\tau} \), then we are done. So, we can suppose that \( x = (\varepsilon, \tau) \) and \( \tilde{x} = (\tilde{\varepsilon}, \tilde{\tau}) \) are near \( \alpha_+ \) and \( \varepsilon, \tilde{\varepsilon} > 0 \). If \( \tilde{\varepsilon} \geq 3/4\varepsilon \), then \( \tilde{\tau} \geq (9/16)\eta\varepsilon^2 \) so that \( \tilde{\tau} - \tau \geq (5/16)\eta\varepsilon^2 \).

Otherwise, \( \tilde{\varepsilon} \leq 3/4\varepsilon \). Since the vertical cones \( K''(x) \) have slope \( d\tau/d\varepsilon \geq \varepsilon(\varepsilon)/3 \) this forces that \( \tilde{\tau} - \tau \geq (1/16)\varepsilon^2 \).

For any \( x \in \xi \setminus \cup \xi_n \), consider the orbit \( x_i = R^ix \). By (10.5), one finds that

\[
|\varepsilon(x_i)| \geq 2\sqrt{\frac{\tau(x_i)}{\eta}} \cdot 2^{-i} \geq 2\sqrt{\frac{\tau(x_i)}{\eta}},
\]

so that any proper vertical curve in \( \mathcal{W}^\omega_{2\tilde{\tau},\eta} \) through \( x_i \) extends beyond \( x_i \) by at least \( K|\varepsilon(x_i)|^2 \geq 4^{-i}K\tilde{\tau}/\eta \).

We now inductively prove that for every \( n \) the curve \( \gamma^n_{x_i} \) extends beyond \( x_i \) by at least \( 4^{-i}K\tilde{\tau}/\eta \). This holds when \( n = 0 \), since \( \gamma^0_{x_i} \) is the proper genuinely vertical interval in \( \mathcal{W}^\omega_{2\tilde{\tau},\eta} \) through \( x_i \). Now suppose that it is true at step \( n \) in order to check for step \( n+1 \). Suppose that some \( \gamma^{n+1}_{x_{i+1}} \) extends beyond \( x_i \) by less than \( 4^{-i}K\tilde{\tau}/\eta \). It implies that \( \gamma^n_{x_{i+1}} \) is not proper, hence \( R: \gamma^{n+1}_{x_{i+1}} \to \gamma^n_{x_{i+1}} \) is a homeomorphism. Since \( R \) contracts the vertical lengths of vertical curves in \( \mathcal{W}^\omega_{2\tilde{\tau},\eta} \) by at least \( q < 1/4 \), this would then imply that \( \gamma^n_{x_{i+1}} \) extends beyond \( x_{i+1} \) by less than \( 4^{-(i+1)}K\tilde{\tau}/\eta \), contradicting the induction hypothesis.

In particular, each of the curves \( \gamma^n_{x_{i+1}} \) extends beyond \( x \) by at least \( K\tilde{\tau}/\eta \), implying that \( \gamma_x \) does as well.

\[\square\]

Remark 10.2. In the above proof we could use the more obvious degree bound by \( 4^n \) instead of the more delicate (10.6) by either selecting \( \eta \) so small that \( q < 1/16 \) or using that \( \lambda = 2 \).

Corollary 10.3. For any \( \eta \in (0, 1/2) \) and \( \delta > 0 \), there exist a threshold \( \tilde{\tau} > 0 \) such that

\[
\text{area } \mathcal{W}^\omega_{\eta,\tilde{\tau}}(T) \geq (1 - \delta) \text{ area } \mathcal{V}_\tilde{\tau}.
\]

Moreover, all the points in \( \mathcal{W}^\omega_{\eta,\tilde{\tau}} \) get attracted to the top of the cylinder exponentially at rate \( O(q^n) \), where \( q = q(\eta) \to 0 \) as \( \eta \to 0 \).

Proof. For each \( \tau \in (0, \tilde{\tau}) \) let \( \xi_\tau = \{ x : \tau(x) = \tau \} \). Applying Lemma 10.2, we find a subset of \( \xi_\tau \) of horizontal measure \( > (2\pi - \delta) \) that converges to \( T \) exponentially at rate \( O(q^n) \). An application of the Fubini Theorem completes the proof. \[\square\]
The proof of Lemma 10.2 actually gives a slightly better statement, which we record here for later use.

For a curve $\xi$, let $\tau(\xi) = \sup_{x \in \xi} \tau(x)$.

**Lemma 10.4.** For any $\eta \in (0, 1/2)$, there exist $\bar{\tau} > 0$ and $C > 1$ such that $W^{s,o}_\eta(T)$ forms at least $3/4$ of the horizontal length of any horizontal curve $\xi$ with $\tau(\xi) \leq \bar{\tau}$ and $l^h(\xi) \geq C \sqrt{\tau(\xi)}$.

**Proof.** By (10.7),

\[ l^h(\xi \setminus W^{s,o}_\eta(T)) \leq \frac{8}{\sqrt{\eta}} \frac{\lambda}{c(\lambda - 1)} \sqrt{\tau(\xi)} \leq \frac{1}{4} C \sqrt{\tau(\xi)}, \]

where we let $C = \frac{32}{\sqrt{\eta}} c(\lambda - 1)$. \hfill $\square$

11. **INTERTWINED BASINS OF ATTRACTION**

Recall the sets $W^{s,o}_\eta(T)$ from §10.2. We let

\[ W^{s,o}_0(T) := \bigcap_{\eta > 0} W^{s,o}_\eta(T). \]

Note that $W^{s,o}_0(T)$ is a completely invariant set whose orbits get attracted to $T$ superexponentially fast.

In this section we will prove the following result:

**Theorem 11.1.** The union of the basins $W^s(B)$ and $W^{s,o}_0(T)$ is a set of full area in the cylinder $C$.

Together with Lemma B.4 we find

**Corollary 11.2.** Almost every point in $W^s(T)$ has characteristic exponent $\log 2$.

11.1. **DISTORTION CONTROL.** To prove Theorem 11.1, we will construct a family of horizontal curves on which $R$ is expanding with bounded distortion. Without the indeterminacy points, this would be straightforward from partial hyperbolicity.

We will remove the union of two wedges extending downward from $\alpha \pm $:

\[ \Delta_k = \{ x \in C : \tau(x) \geq \bar{\kappa}[e(x)] \}. \]

**Lemma 11.3.** Given any $\bar{\kappa} > 0$, there is a family $H_x$ of “admissible” horizontal curves centered each $x \in C$ with the following property:

If the orbit of $x \in C \setminus \{\alpha_\pm\}$ avoids the wedge regions $\Delta_k$, then there a neighborhood $U$ of $\alpha_\pm$ and sequence of times $n_i \equiv n_i(x) \in \mathbb{Z}_+$ such that $R^{n_i}x$ remains outside of $U$ and for any curve $\xi \in H_x$ we have:

(i) $\xi \in H_x$ projects onto the horizontal interval of radius $r(x) \asymp \text{dist}^h(x, \{\alpha_\pm\})$ centered at $x$;

(ii) The image $R^{n_i}\xi$ overflows some curve $\eta_i \in H_{R^{n_i}x}$;

(iii) If $\tilde{\eta}_i$ is the restriction of $\eta_i$ to one half of its radius, then, the inverse branch $R^{-n_i} : \tilde{\eta}_i \rightarrow \xi$ is uniformly exponentially contracting with bounded distortion (with the contracting factor going to 0 as $n_i \rightarrow \infty$).

Moreover, the genuinely horizontal intervals

\[ \{ J_x = (\phi, t) : t = t(x), |\phi - \phi(x)| < r(x) \} \]

are admissible.
11.2. **Proof of Theorem 11.1.** Let us first derive Theorem 11.1 from Lemma 11.3.

Take a small $\eta \in (0, 1/2)$ and let $X_\eta$ be the complement of $W^u(B) \cup W^u_{\eta}(T)$. Assume area($X_\eta$) > 0. By the Lebesgue and Fubini Theorems, there is a point $x \in X_\eta$ which is a density point for the slice of $X_\eta$ by any genuinely horizontal interval $J = J_x$ centered at $x$.

By Proposition 9.5, we can choose $\bar{\kappa}$ sufficiently large so that the wedge regions $\Delta_{\bar{\kappa}}$ are entirely contained in $W^u(B)$. Since $x \notin W^u(B)$, the orbit $x_\eta := R^n x$ avoids $\Delta_{\bar{\kappa}}$, allowing us to apply Lemma 11.3.

Let $S \subset \mathbb{N}$ be the subsequence of times $n_i \equiv n_i(x)$ given by Lemma 11.3. We can choose a further subsequence $S' \subset S$ along which $x_{n_i}$ converges to some $y \in C \setminus \{\alpha_{\pm}\}$. We will keep the same notation $n_i$ for this subsequence.

Now, let $J$ be the genuinely horizontal interval radius $r(x)$. Since $J$ is admissible, for any $n_i \in S'$ there is an admissible curve $\eta_i \in \mathcal{H}_{x_{n_i}}$, centered at $x_{n_i}$ such that the inverse branch $R^{-n_i} : \eta_i \to J$ is contracting (exponentially in $n_i$) with bounded distortion.

Suppose $y \notin T$. Then, the curves $\tilde{\eta}_i$ are part of a compact family of curves having the property that each curve from the family intersects $W^u(B)$ in a dense open set. This implies that $W^u(B)$ occupies a definite portion of each $\tilde{\eta}_i$. Since $R^{-n_i} : \tilde{\eta}_i \to J$ has a bounded distortion, the basin $W^u(B)$ occupies a definite portion of $R^{-n_i}(\tilde{\eta}_i)$, which is can be made an arbitrarily small neighborhood of $x \in J$ by taking $n_i$ sufficiently large. This contradicts the choice of $x$ as a density point of $X_\eta$ on $J$.

If $y \in T$, then let us consider $\bar{r} > 0$ and $C > 1$ from Lemma 10.4. Since $\tilde{\eta}_i$ is a horizontal curve (with respect to the algebraic cone field $\mathcal{K}^{ah}$), the horizontal length of $\gamma := \tilde{\eta}_i \cap V_\epsilon$ is at least $\sqrt{r}$ for $n_i \in S'$ sufficiently big, since it lies above one of the parabolas $S_\psi$. Since $\gamma$ is near $T$ and bounded away from $\alpha_{\pm}$, Lemma 10.4 gives that the horizontal length of $\gamma' := R \gamma$ is at least that big. But $\tau(\gamma') = O(\bar{r}^2)$, so $l^h(\gamma') \geq C \sqrt{r(\gamma')}$. By Lemma 10.4, $W^u_{\eta}(T)$ occupies at least $3/4$ of $\gamma'$.

Since $\gamma$ is bounded away from $\alpha_{\pm}$, the single iterate $R : \gamma \to \gamma'$ has bounded distortion (as does its inverse). Therefore, $R^{-n_i+1} : \gamma' \to J$ is exponentially contracting with bounded distortion. Hence, by taking sufficiently large $i$, the basin $W^u_{\eta}(T)$ occupies a definite portion of the arbitrarily small neighborhoods $R^{-n_i+1}(\gamma') \subset J$ of $x$, contradicting again the choice of $x$.

The contradictions show that area($X_\eta$) = 0 for any $\eta > 0$, and the conclusion follows. □

11.3. **Proof of Lemma 11.3.** Let us formulate a stronger, complex version of Lemma 11.3. Here “horizontal holomorphic curves” are understood in the sense of the complex extension of the horizontal cone field $\mathcal{K}^{ah}$ constructed in Appendix C.

Let $\pi(z, w) = z$.

**Lemma 11.4.** Given any $\bar{\kappa} > 0$, there is a family $\mathcal{H}_x$ of “admissible” horizontal holomorphic curves entered at each $x \in C$ with the following property:

If the orbit of $x \in C \setminus \{\alpha_{\pm}\}$ avoids the wedge regions $\Delta_{\bar{\kappa}}$, then there is a neighborhood $U$ of $\alpha_{\pm}$ and a sequence of times $n_i \equiv n_i(x) \in \mathbb{Z}_+$ such that $R^n x$ remains outside of $U$ and for any curve $\xi \in \mathcal{H}_x$ we have:

(i) $\xi \in \mathcal{H}_x$ projects under $\pi$ on a complex disc of radius $r(x) = \dist^h(x, \{\alpha_{\pm}\})$ centered at $\pi(x)$.

(ii) The image $R^n \xi$ overflows some curve $\eta_\xi \in \mathcal{H}_{R^n x}$.
(iii) If $\tilde{\eta}_i$ is the restriction of $\eta_i$ to one half of its radius, then, the inverse branch $R^{-n_i} : \tilde{\eta}_i \to \xi$ is uniformly exponentially contracting with bounded distortion (with the contracting factor going to 0 as $n_i \to \infty$).

Moreover, the genuinely horizontal discs

$$\{D_x = (\phi, t) : t = t(x), |\phi - \phi(x)| < r(x)\}.$$ are admissible.

Proof. If $x \in C \setminus U$, then $H_x$ will consist of all horizontal holomorphic curves $\xi$ that project under $\pi$ onto the round disc of constant radius $r(x) = r_1$ (to be specified below) centered at $\pi(x)$. If $x \in U$, then $H_x$ will consist of the restrictions to half their radius of all horizontal holomorphic curves that project under $\pi$ onto a round disc of radius $a|e(x)|$.

Since $R$ is horizontally expanding (Theorem 8.1), there is an $N$ such that $DR^n$ expands horizontal vectors $v \in K^{ah}(x)$, $x \in C \setminus \{\alpha_{\pm}\}$, by definite factor.

We can choose a neighborhood $U \subset C$ of $\{\alpha_{\pm}\}$ sufficiently small so that each of the preimages $R^{-n} U$ for $1 \leq n \leq N$ is in the neighborhood $V'$ of $T$ in which Lemma B.4 gives that each iterate of $R$ expands horizontal vectors. Therefore, if $x \in C \setminus U$ there exists $n(x) \leq N$ so that $DR^n(x)$ expands any $v \in K^{ah}(x)$ and $R^n x \notin U$ for $0 \leq n(x)$. By continuity, we can also require that $R^n x \notin U$ for $0 \leq n(x)$.

Proposition C.4 gives $C > 0$ so for any sufficiently small $a > 0$ and any $x \in U$ with $|\kappa(x)| < \bar{\kappa}$ there is an iterate $n(x)$ so that if $\xi$ is an horizontal holomorphic curve centered at $x$ of radius $a|e(x)|$ and $\xi_0$ is the subdisc of radius $a|e(x)|/2$, then $R^n(x) \xi_0$ is horizontal and projects under $\pi$ onto a disc has a definite radius $\geq C a$. We further restrict $U$ so that $|e(x)| < C$ for any $x \in U$. It ensures that $R^n(x) \xi_0$ will be larger than any curve $\xi$ of radius $a|e(x)|$ that is based at any $x \in U$.

Since the cone-field $K^{ah}$ is defined in a definite complex neighborhood of $C \setminus U$, on which $DR$ has bounded expansion, we can choose $r_0$ sufficiently small for any horizontal holomorphic curve $\xi$ centered at $x \in C \setminus U$ of radius $\geq r_0$ we have that $R^{\xi}$ is in the domain of definition of $K^{ah}$ for $1 \leq n \leq N(x)$. In particular, $R^n(x) \xi$ will be horizontal. By continuity, we can also require that $r_0$ be sufficiently small so that $R^n(x)$ is uniformly expanding on any such curve $\xi$.

If we choose $a$ sufficiently small so that $C \cdot a < r_0$ and choose $r_1 = C \cdot a$, it will guarantee the overflowing property (ii).

The above gives a sequence of further times $n_i(x)$ and curves $\eta_i \in H_{R^{n_i}(x)} x$ so that $R^{n_i+1}(x) \eta_i$ is horizontal and overflows $\eta_{i+1}$. Consequently, the inverse $R^{-n_i}(x) \eta_i \to \xi$ is well-defined (and hence univalent) for each $i$.

The Koebe Distortion Theorem gives that the restriction $R^{-n_i}(x) \tilde{\eta}_i \to \xi$ of each inverse branch to the disc of half the radius will have bounded distortion. By construction, $DR^n(x)$ is exponentially expanding at the center of $\xi$, therefore the inverse branch is exponentially contracting.

It follows from the proof of Proposition C.4 that if $R^n(x) x \in U$, then $R^{n+1}(x) x \notin U$. Therefore, passing to a subsequence, we can suppose that $R^n(x) x \notin U$ for each $i$.

Remark 11.1. The whole proof of Lemma 11.4 goes through in the purely real way except one problematic point: the distortion control in (iv). In fact, with some extra work it should be possible to do it as well, using the property that the horizontal non-linearity of $R$ behaves like $1/\epsilon$ near the indeterminacy points $\alpha_{\pm}$.
12. Central foliation, its holonomy and transverse measure

In what follows all laminations in question will be assumed strictly vertical. Given a lamination $\mathcal{F}$ and $\tau \in (0, 1)$, we let $\mathcal{F}_\tau$ be the slice of $\mathcal{F}$ by the truncated cylinder $\mathcal{C}_\tau = \mathbb{T} \times [0, 1 - \tau]$.

12.1. Central foliation. Recall that central foliation is a strictly vertical foliation invariant under $\mathcal{R}^\ast$.

**Theorem 12.1.** The map $\mathcal{R}$ has a unique central foliation.

**Proof.** According to Proposition 7.7, through each $x \in \mathcal{C} \setminus \{\alpha_{\pm}\}$ is a central curve extending in both directions to the boundary of the cylinder. Taking the union of all such curves through every point on $\mathcal{C}_1$, we obtain an invariant family $\mathcal{F}^c$ of strictly vertical $C^1$-curves filling in the whole cylinder $\mathcal{C}_1$.

However, for a continuous vector field, there may exist many integral curves through a given point, so $\mathcal{F}^c$ may fail to be a foliation. What saves the day is that $\mathcal{R}$ is horizontally expanding (Theorem 8.1). Namely, assume that there exist two integral curves, $\gamma_1$ and $\gamma_2$, through a point $x \in C_1$. Let us take two points $y_i \in \gamma_i$ on the same height, and connect them with a (genuinely) horizontal interval $\delta = [y_1, y_2]$. By Theorem 8.1, the curves $\delta_n := \mathcal{R}^n(\delta)$ are almost horizontal, and $l^h(\delta_n) \to \infty$. Hence the horizontal projections of the $\delta_n$ eventually cover the whole circle $\mathbb{T}$, and in particular, they intersect the critical interval $I_{\pi/2}$. Hence $\delta$ intersects $(\mathcal{R}^\ast)^n(\mathcal{I}_{\pi/2})$ at some point $y$.

But the interval $I_{\pi/2} \setminus \{\alpha_{\pm}\}$ is contained in the basin of $\mathcal{B}$, where $\mathcal{F}^c$ coincides with the stable foliation $\mathcal{F}^s(\mathcal{B})$, which is a $C^\infty$ foliation (Proposition 9.11). Pulling it back, we conclude that there is a unique integral curve $\mathcal{W}^c(y)$ through $y$, and $\mathcal{F}^c$ is a $C^\infty$ foliation near it. But $\mathcal{W}^c(y)$ is squeezed in between the curves $\gamma_1$ and $\gamma_2$, and hence must merge with them at $x$ — contradiction.

This proves that the line field $\mathcal{L}^c$ is uniquely integrable, so the family $\mathcal{F}^c$ of all integral curves forms the central foliation. Since any such foliation must be formed by integral curves to $\mathcal{L}^c$, it is unique. \qed

Recall from the Introduction that the holonomy transformations $g_t : \mathcal{B} \to \mathbb{T}_t \equiv \mathbb{T} \times \{t\}, \ t \in [0, 1)$, are defined by the property that $x$ and $g_t(x)$ belong to the leaf of $\mathcal{F}^c$.

**Remark 12.1.** By means of the holonomy along the central foliation to the bottom of $\mathcal{C}$, we can now obtain a continuous extension $\Phi : \mathcal{C}_1 \to \mathbb{T}$ of the Böttcher coordinate that was constructed in §9.7 (namely, let $\Phi(\phi, t) = g_t^{-1}(\phi)$). Since $\mathcal{F}^c$ is $\mathcal{R}$-invariant, $\Phi$ also satisfies the Böttcher functional equation $\Phi(\mathcal{R}(\phi, t)) = 4\Phi(\phi, t)$. However, $\Phi$ has weak regularity outside of $\mathcal{W}^s(\mathcal{B})$: for example, it is not even absolutely continuous (see Corollary 12.10 below).

12.2. Central tongues. Recall a notion of a tongue from §9.4. A tongue is called central if it is bounded by two central leaves (and hence it is saturated by intermediate leaves of the central foliation $\mathcal{F}^c$). For instance, the primary central tongues $\Lambda_{\pm}$ from Property (P6) in §3.3 are central tongues in this sense (as they are bounded by $\mathcal{R}$-lifts of $\mathcal{I}_x$, which are central leaves).

Recall also the pre-indeterminacy set $\mathcal{A} = \cup \mathcal{A}^n$ (9.2).

**Proposition 12.2.** There is one maximal central tongue $\Lambda(\alpha)$ attached to each pre-indeterminacy point $\alpha \in \mathcal{A}^n$, which is the regular pullback of one if the tongues
$\Lambda_\pm \equiv \Lambda(\alpha_\pm)$ by $f^n$. This family of tongues is dense in $C$, and any central tongue is contained in one of these.

**Proof.** Obviously, regular lifts of central tongues are central tongues. Lifting the $\Lambda_\pm$, we obtain a family of central tongues $\Lambda(\alpha)$ attached to points $\alpha \in \mathcal{A}$. These tongues are pairwise disjoint as they are attached to different points of $T$. Moreover, a central tongue $\Lambda(\alpha)$ with $\alpha \in \mathcal{A}$ has the bottom of length $\pi/2^{2n+1}$. Since $|\mathcal{A}| = 2^{n+1}$, we have:

$$\sum |B_{\Lambda(\alpha)}| = \sum_{n=0}^{\infty} \frac{\pi}{2^n} = 2\pi,$$

so the bottoms of these tongues have full measure in $B$. Hence this family of tongues is dense in $C$. So, there is no room for enlarging these tongues, nor for fitting any extra tongue in between. \qed

### 12.3. Orbits of typical leaves

Given $x \in C$, for each $n \geq 0$ let $\gamma_n(x) \in F^c$ be the leaf containing $R^n x$. Invariance of $F^c$ gives $R\gamma_n(x) \subset \gamma_{n+1}(x)$. Note that we can have $R\gamma_n(x) \subsetneq \gamma_{n+1}(x)$ if $\gamma_n(x)$ meets $T$ at $\alpha_\pm$.

**Proposition 12.3.** For almost every $x \in C$ have either:

(i) there exists $N \geq 0$ so that for all $n \geq N$: $\gamma_n(x)$ meets $T$ away from $\alpha_\pm$, $R\gamma_n(x) = \gamma_{n+1}(x)$, there are non-trivial intervals of points on $\gamma_n$ converging superexponentially to $B$ and to $T$, or

(ii) $\gamma_n(x) \subset W^s(B)$ for all $n \geq 0$.

**Proof.** According to Theorem 11.1, almost every $x \in C$ is in $W^s(B) \cup W^u_0(T)$. It will be helpful later if we also assume that $x \not\in T$.

If $x \in W^s_0(T)$, then for any $\tau, \eta > 0$ there exits $N \geq 0$ so that $R^n x \in W^s_{\tau, \eta}(T)$ for all $n \geq N$. (See §10.2.) For such $n$, some portion of $\gamma_n$ agrees with a curve from the stable lamination of $W^s_{\tau, \eta}(T)$ constructed in the proof of Proposition 10.1. In particular, $\gamma_n$ meets $T$ away from $\alpha_\pm$, and hence $R(\gamma_n) = \gamma_{n+1}$.

Any leaf of $F^c$ intersects $W^s(B)$ in a non-trivial interval. Meanwhile, $R^n x$ has orbit superattracted to $T$, so all points on $\gamma_n$ above $R^n x \not\in T$ have orbits that converge superexponentially to $T$.

Now suppose $x \in W^s(B)$. Let $B_0 = \cup R^{-n}(B_{T_\pm})$, where $B_{T_\pm}$ are the bottoms of the primary stable tongues. By Proposition 9.6, $B_0$ has full Lebesgue measure. Since $z \mapsto z^4$ preserves Lebesgue measure, the Poincaré Recurrence Theorem gives that the set of points $B_0 \subset B_0$ whose orbits return infinitely many times to $B_0$ has full Lebesgue measure in $B_0$. Hence it also has full measure in $B$.

For any $x \in B_0$, there is an infinite sequence of times $n_i$ for which $R^{n_i} x \in B_0$, implying $\gamma_{n_i}(x) \subset W^s(B)$. Then, because of the invariance $R(\gamma_{n_i}(x)) \subset \gamma_{n_i+1}(x)$, we have $\gamma_n(x) \subset W^s(B)$ for all $n$.

Therefore, it suffices to prove that almost every point of $W^s(B)$ is in $\bigcup_{x \in B_0} \gamma(x)$. However, this follows since $F^c = C^\infty$ on $W^s(B)$ and that $B_0$ has full Lebesgue measure in $B$. \qed

### 12.4. Convergence

Given a metric space $M$, the Hausdorff metric on the space of closed subsets of $M$ is defined as follows: $\text{dist}_H(X, Y)$ is the infimum of $\epsilon > 0$ such that $X$ is contained in the $\epsilon$-neighborhood of $Y$, and the other way around.

We say that a sequence of strictly vertical laminations $F^n$ converges to a lamination $F$ if they converge in the Hausdorff metric on subsets of the space $C^0[0, 1]$. 

Convergence is called exponentially with rate $\lambda \in (0, 1)$ is there exists $C > 0$ such that
\[ \text{dist}_H(\mathcal{F}^n, \mathcal{F}) \leq C\lambda^n. \]

**Theorem 12.4.** For any strictly vertical lamination $\mathcal{F}$, the pullbacks $\mathcal{F}^n := (\mathcal{R}^n)^* \mathcal{F}$ converge exponentially (with the same rate) to the central foliation $\mathcal{F}^c$ of $\mathcal{R}$.

**Proof.** Given any $\gamma \in \mathcal{F}^c$, let $\gamma_i$ be the curve from $\mathcal{F}^c$ containing $\mathcal{R}^i \gamma$ for $i = 1, \ldots, n$. Let $\eta_n$ be any leaf from $\mathcal{F}$. We choose a sequence of preimages $\eta_{n-1}, \ldots, \eta_0$, so that $\eta_{-1}$ is obtained from $\eta_i$ under the same inverse branch of $\mathcal{R}$ as $\gamma_{i-1}$ is obtained from $\gamma_i$. Let $h_0$ be the shorter of the two segments on $\mathcal{B}$ connecting from $\gamma_0$ to $\eta_0$. By construction, $l^h(h_0) \leq \pi/4^n$.

For any $t \in [0, 1]$, let $h_t$ be the genuinely horizontal curve from $\gamma(t)$ to $\eta(t)$ chosen so that $\gamma(0, t] \cup h_t \cup [0, t]$ and $h_0$ are homotopic (relative to their endpoints) on $\mathcal{C}$. Then, their iterates under $\mathcal{R}^n$ are also homotopic. The horizontal length of any vertical curve in $\mathcal{C}$ is bounded by some constant $K$. Therefore, since $\mathcal{R}^n \gamma(0, t] \cup h_t$ are vertical, we have that $l^h(\mathcal{R}^n h_t) \leq l^h(\mathcal{R}^n h_0) + 2K \leq \pi + 2K$.

Using horizontal expansion, Theorem 8.1, we have $l^h(h_t) \leq C\lambda^{-n} \cdot l^h(\mathcal{R}^n h_t)$ for appropriate $C > 0$ and $\lambda > 1$. Since $l^h(\mathcal{R}^n h_t) \leq \pi + 2K$, we have $l^h(h_t) \leq 2\lambda^{-n}$. Therefore, given any $\gamma \in \mathcal{F}^c$ there is some $\eta \in \mathcal{F}^n$ that is $2\lambda^{-n}$ close within $C^n[0, 1]$.

After switching the roles of $\gamma$ and $\eta$, the same proof shows that given any $\eta \in \mathcal{F}^n$ there is some $\gamma \in \mathcal{F}^c$ that is $D\lambda^{-n}$ close within $C^n[0, 1]$. \qed

**Corollary 12.5.** The sequence of Lee-Yang loci $\mathcal{S}_n$ converges exponentially to the central foliation $\mathcal{F}^c$.

We have a better convergence at low temperatures. For any $\epsilon > 0$ let $\mathcal{F}^n_{\epsilon}$ and $\mathcal{F}_{\epsilon}$ the truncations of $\mathcal{F}^n$ and $\mathcal{F}$ to the cylinder $\mathbb{T} \times [0, t_{\epsilon} - \epsilon]$.

**Proposition 12.6.** For any $\epsilon > 0$ we have exponential convergence
\[ \text{dist}_H(\mathcal{F}^n_{\epsilon}, \mathcal{F}_{\epsilon}) \leq C(\epsilon) \lambda^n \]
where $\text{dist}_H$ denotes the Hausdorff metric on subsets of $C^1[0, 1 - \epsilon]$.

**Proof.** Given any $\gamma \in \mathcal{F}^c$, let $\eta \in \mathcal{F}^n$ be the curve constructed in the proof of Theorem 12.4. Let $t \in [0, t_{\epsilon} - \epsilon]$. By Lemma 7.3, $\eta(t)$ is exponentially close to $\mathcal{L}^c(\eta(t))$. Since $\gamma(t)$ and $\eta(t)$ are exponentially close and $\mathcal{L}^c$ is Hölder in $W^1(\mathcal{B})$ (see Proposition 9.11) $\gamma(t) = \mathcal{L}^c(\gamma(t))$ and $\mathcal{L}^c(\eta(t))$ are also exponentially close. \qed

### 12.5. Holonomy and the transverse measure.

#### 12.5.1. Regularity of the holonomy.

**Proposition 12.7.** All holonomy transformations $g_t$, $0 \leq t < 1$, are uniformly Hölder continuous homeomorphisms. If $y = g_t(x) \in W^1(\mathcal{B})$ then $g_t$ is a $C^\infty$ local diffeomorphism near $x$.

**Proof.** Let us take an interval $J \subset \mathcal{B}$, and let $J_t = g_t(J)$. Since $\mathcal{R}(z) = z^4$ on $\mathcal{B}$, there is an $n \in \mathbb{N}$ such that $\mathcal{R}^n(J)$ covers $\mathbb{T}$ at least once, but no more than four times. Then the same is true for $\mathcal{R}^n(J_t)$. Hence the horizontal length of both intervals $\mathcal{R}^n(J)$ and $\mathcal{R}^n(J_t)$ is squeezed in between $2\pi$ and $8\pi$. It follows that $l(J) \asymp 4^{-n}$, while $l(J_t) = O(\lambda^{-n})$ with $\lambda > 1$ from Theorem 8.1. Hence $l(J_t) = O(l(J)^\sigma)$ with $\sigma = \log \lambda/\log 4$. 
Corollary 12.10. The holonomy maps \( g_t : \mathcal{B} \to \mathbb{T}_t \) are absolutely continuous, while the inverse maps \( g_t^{-1} \) are not for \( t > t_c \).

Proof. Absolute continuity of \( g_t \) is equivalent to absolute continuity of the push-forward measure \( \mu_t = (g_t)_* \mu_0 \), so Proposition 12.9 implies the first assertion.

On the other hand, by Theorem 10.3, the complement to the stable tongues on any section \( \mathbb{T}_t, t > t_c \), has positive measure, while on the bottom \( \mathcal{B} \), it has measure zero (by Proposition 9.6 (v)). This yields the second assertion. \( \square \)

At the top, the transverse measure becomes purely atomic:
Proposition 12.11. As \( t \to 1 \), the distributions \( \mu_t \) weakly converge to the distribution \( \mu_1 \) supported on the pre-indeterminacy set \( \mathcal{A} \) that assigns to a point \( \alpha \in \mathcal{A} \) weight \( \frac{1}{4^{n+1}} \).

Proof. This follows from Proposition 12.8, taking into account that \( \mu_0(B_{\Lambda_0}) = \frac{1}{4^{n+1}} \).

12.6. High-temperature hairs and critical points. As usual, we parameterize each \( \gamma \in \mathcal{F}_c \) by temperature \( t \). Every \( \gamma \in \mathcal{F}_c \setminus \{I_{\pm \pi/2}\} \) maps by \( \mathcal{R} \) homeomorphically onto \( \mathcal{R}(\gamma) \), so there are temperatures \( 0 < \gamma^- \leq t \leq 1 \) so that

\[
\gamma \cap \mathcal{W}^s(B) = \gamma[0, \gamma^-) \quad \text{and} \quad \gamma \cap \mathcal{W}^s(T) = \gamma(t^+, 1] \text{ or } \gamma[\gamma^-, t^+].
\]

We call \( h_\gamma := \gamma \cap \mathcal{W}^s(T) \) the high-temperature hair contained in \( \gamma \). Recall the notion of Cantor bouquet introduced in §10.1.

Proposition 12.12. \( \mathcal{W}^s(T) \) is a Cantor bouquet containing all of the bouquets that were constructed in §10.1.

We call \( e_\gamma := \gamma(t^+_\gamma) \) the endpoint of \( h_\gamma \) and \( c_\gamma := \gamma([t^-_\gamma, t^+_\gamma)) \) the critical points of \( \gamma \). Let

\[
\mathcal{E} := \bigcup_{\gamma} e_\gamma \quad \text{and} \quad \mathcal{C} := \bigcup_{\gamma} c_\gamma
\]

Each is an \( \mathcal{R} \) invariant set.

Proposition 12.13. The set of critical temperatures \( \mathcal{C} \) has zero Lebesgue measure.

Proof. By construction, the high temperature hair through any \( x \in \mathcal{W}^s(T) \) extends below \( x \). Therefore, \( \mathcal{C} \) lies in the complement of \( \mathcal{W}^s(B) \cup \mathcal{W}^s_0(T) \) so that it has measure 0 by Theorem 11.1.

Corollary 12.14. The set of endpoints to the high-temperature hairs \( \mathcal{E} \) has zero Lebesgue measure.

13. Lee-Yang Distributions, Local Rigidity, and Critical exponents

Now, having plowed hard in the RG dynamical cylinder, let us collect the physics harvest:

13.1. Lee-Yang Distributions and Critical exponents. Proof of the Main Theorem (physical version). Recall from §1.3 that the Lee-Yang locus \( \mathcal{S}_n \) of level \( n \) is equal to the pullback \( (\mathcal{R}^n)^* \mathcal{S}_0 \) of the principal LY locus \( \mathcal{S} \equiv \mathcal{S}_0 (3.8) \). By Theorem 12.4, these loci converge exponentially fast to the central foliation \( \mathcal{F}_c \).

Moreover, on the bottom \( \mathcal{B} \) the Lee-Yang zeros are obviously asymptotically equidistributed with respect to the Lebesgue measure \( \mu_0 \). It follows that on the circle \( \mathcal{T}_t \), they are asymptotically equidistributed with respect to the measure \( (\mu_t)_*(\mu_0) = \mu_t \), which is the standard transverse measure for \( \mathcal{F}_c \). The rest of the physical version of the Main Theorem follows from the properties of \( \mu_t \) established in §12.
13.2. Local Rigidity. Recall the notion of local rigidity introduced in §1.2.

**Proposition 13.1.** The Lee-Yang zeros for the DHL are locally rigid at any point where the limiting density is positive \( \rho(\phi, t) > 0 \).

**Proof.** The Lee-Yang zeros \( \phi^n_k(t) \) of level \( n \) on \( T_t \) are the solutions to

\[
(13.1) \quad h^n_k(\phi) := \frac{1}{2 \cdot 4^n} f_1 \circ R^n(\phi, t) = \frac{\pi k}{4^n} + \frac{\pi}{2 \cdot 4^n}, \quad k = 0, 1, \ldots 2 \cdot 4^n - 1,
\]

where \( f_1 : C \to T \) is the first coordinate of the mapping \( f \) given in (3.3). Notice that \( f_1 \) is a degree 2 map tangent to \( 2\phi \) on \( B \).

Fix a point \( x = (\phi_*, t) \in W^s(B) \) and a closed horizontal interval \( J_t \subset O_t \) containing \( x \) in its interior.

By Lemma 9.14, the maps \( h^n_k \) converge in the \( C^1 \) topology on \( J \) to the Böttcher coordinate \( \Phi_t(\cdot) \equiv \Phi(\cdot, t) \). Since \( \partial \Phi / \partial \phi \neq 0 \), the maps \( h^n_k \) are invertible on \( J_t \) for sufficiently large \( n \). Let \( g^n_t : J_0 \to J_t \) be the inverse (where \( J_0 := h^n_k(J) \subset B \)). Since the holonomy map \( g_t \) is the inverse of \( \Phi_t \), we conclude that \( (g^n_t)' \to g_t' \) uniformly on \( J_0 \).

For each \( n \), let \( \phi^n_k \) be the Lee-Yang zero that is closest to \( \phi_* \). We will show that the rescaled Lee-Yang zeros

\[
(13.2) \quad s^n_k = \frac{2 \cdot 4^n}{2\pi} \rho_t(\phi_*)\left( \phi^n_{t+k} - \phi^n_k \right),
\]

converge locally uniformly to the integer lattice \( \mathbb{Z} \).

After fixing \( k \), \( \phi^n_{t+k} \) and \( \phi^n_k \) will be in \( J \) for all \( n \) sufficiently large. The Mean Value Theorem gives

\[
(13.3) \quad \phi^n_{t+k} - \phi^n_k = (g^n_t)'(\phi_*) \left( \psi^n_k \right) \frac{2\pi k}{2 \cdot 4^n},
\]

where \( \psi^n_k \) is between \( \frac{n}{2\pi} + \frac{\pi}{2 \cdot 4^n} \) and \( \frac{n+1}{2\pi} + \frac{\pi}{2 \cdot 4^n} \).

Equation (13.2) becomes

\[
(13.4) \quad s^n_k = k \cdot (g_t^{-1})'(\phi_*). \quad \text{For fixed } k, \quad \lim \psi^n_k = \Phi(\phi_*) = (g_t)^{-1}(\phi_*).
\]

Thus, \( (g^n_t)'(\psi^n_k) \to g_t((g_t)^{-1}(\phi_*)) \) giving that \( s^n_k \to k \). \( \square \)

13.3. Critical Exponents. Let \( x = (z, t) \in C \setminus W^s(B) \) (so that the density \( \rho_t \) of the transverse measure \( \mu_t \) vanishes at \( x \)). If

\[
(13.5) \quad \mu_t(J) \asymp |J|^{\sigma^h+1}
\]

for a horizontal interval \( J \) containing \( x \) on its boundary, then \( \sigma^h = \sigma^h(x) \) is called the horizontal critical exponent of the transverse measure at \( x \) (on the left- or right-hand side of \( x \), depending on \( J \) - if we do not specify the side, it means that the critical exponent exists on both sides).

Let additionally, \( x \) lie on the boundary point of \( L^c(x) \cap W^s(B) \) (in other words, let all points on the central leaf \( L^c(x) \) below \( x \) converge to the bottom of the cylinder). If

\[
(13.6) \quad \rho(y) \asymp \text{dist}(x, y)^{\sigma^v} \quad \text{for } y \in L^c(x) \text{ below } x,
\]

then \( \sigma^v \) is called the vertical critical exponent of the transverse measure at \( x \).

Let \( x \) be a periodic point for \( \mathcal{R} \) of period \( p \) with multipliers \( \lambda^u > \lambda^c \). Here the unstable multiplier \( \lambda^u \) corresponds to the eigenvector of \( DR_j^p \) in the horizontal
cone $K^h(x)$, while the central multiplier corresponds to the eigenvector tangent to the central leaf $L^c(x)$. The inequality between the multipliers follows from the dominated splitting. Also, $\lambda^n > 1$ because of the horizontal expansion. The corresponding characteristic exponents at $x$ are defined as
\[
\chi^u(x) = \frac{1}{p} \log \lambda^u, \quad \chi^c(x) = \frac{1}{p} \log \lambda^c.
\]

**Proposition 13.2.** Let $x$ be a periodic point for $R$ of period $p$ with the characteristic exponents $\chi^u$ and $\chi^c$. Then
\[
\sigma^h(x) = \frac{\log 4}{\chi^u} - 1.
\]
Moreover, if $x$ is a boundary point of some component $J$ of the basin $O_t$, then
\[
\rho_t(y) \asymp \text{dist}(x, y)^{\sigma^h}, \quad y \in J \text{ near } x.
\]
If $x$ is the boundary point of $L^c(x) \cap \mathcal{W}^s(B)$ and $\chi^c(x) > 0$, then
\[
\sigma^u(x) = \frac{\log 4 - \chi^u}{\chi^c}.
\]

**Proof.** Given a horizontal interval $J \ni x$, let us apply to it an iterate $R^n$ that stretches $J$ to a horizontal curve that wraps around the cylinder at least once but at most four times. Then both $l^h(R^n(J))$ and $\mu(R^n(J))$ are comparable with 1.

On the other hand, $l^h(R^n(J)) \asymp \exp(n\chi^u)|J|$ while $\mu(R^n(J)) = 4^n \mu_t(J)$. Hence $\mu_t(J) \asymp |J|^\sigma$ with exponent $\sigma = \log 4/\chi^u - 1$. This proves (13.7).

Let us prove (13.8). Iterating the transfer rule (12.3), we obtain:
\[
4^n \rho(y) = \lambda^n_h(y) \rho(R^n y), \quad \text{where } \lambda^n_h(y) = \prod_{k=0}^{n-1} \lambda^h(R^k y).
\]

Let $y \in J$ be a point near $x$. Because of the horizontal expansion, we can find an iterate $R^n$ such that $\text{dist}^h(R^n x, R^n y) \asymp 1$. Then $\rho(R^n y) \asymp 1$, while $\lambda^n_h(y) \asymp \exp(n\chi^u(x))$. Incorporating these into (13.10), we obtain:
\[
\rho(y) \asymp \exp(n(\chi^u - \log 4)).
\]

On the other hand, $\text{dist}(x, y) \asymp \exp(-n\chi^u(x))$, and (13.8) follows.

To prove (13.9), take a point $y \in L^c(x)$ below $x$. Then $y \in \mathcal{W}^s(B)$ since $x$ lies on the boundary of $L^c(x) \cap \mathcal{W}^s(B)$. Hence we can find an iterate $R^n$ such that $\text{dist}^c(R^n x, R^n y) \asymp 1$. However, in this case $x$ repels $y$ at exponential rate with exponent $\chi^c$, so $\text{dist}(x, y) \asymp \exp(-n\chi^c(x))$, and (13.9) follows. \hfill \square

**Corollary 13.3.** The horizontal and vertical critical exponents at the fixed point $\beta_c = (0, t_c) \in \mathcal{I}_0$ are equal to $\sigma^h(\beta_c) = 0.06431 \ldots$ and $\sigma^v(\beta_c) = 0.1617 \ldots$.

One can define the critical exponents at a point $x \in \mathcal{W}^s(T)$ in a weak sense:
\[
\sigma^h(x) = \lim_{|J| \to 0} \frac{\log \mu(J)}{\log |J|} - 1, \quad \sigma^v(x) = \lim_{y \to x} \frac{\log \rho(y)}{\log \text{dist}(x, y)}
\]
(if the limits exist), where the meaning of $J$ and $y \in L^c(x) \cap \mathcal{W}^s(x)$ are the same as in formulas (13.5), (13.6). These critical exponents can be expressed in terms of the unstable and central Lyapunov exponents
\[
\chi^h(x) = \lim_{n \to \infty} \frac{1}{n} \log \lambda^h_n(x), \quad \chi^h(x) = \lim_{n \to \infty} \frac{1}{n} \log \lambda^h_n(x)
\]
by the same formulas as in the case of periodic points:

**Proposition 13.4.** Let $x \in \mathcal{C} \setminus \mathcal{W}^u(\mathcal{B})$ be a point with the unstable Lyapunov exponent $\chi^u$. Then the horizontal critical exponent $\sigma^h(x)$ exists in the weak sense and is given by formula (13.7). Moreover, if $x$ is a boundary point of some component $J$ of the basin $O_t$, then

$$\sigma^h(x) = \lim_{y \to x} \frac{\log \rho_t(y)}{\log \text{dist}(x, y)} \quad \text{as } y \to x, \ y \in J.$$  

If $x$ is the boundary point of $\mathcal{L}^c(x) \cap \mathcal{W}^u(\mathcal{B})$ and the central Lyapunov exponent $\chi^c(x)$ exists and positive, then the vertical critical exponent $\sigma^v(x)$ exists in the weak sense and is given by formula (13.9).

The proof mimics that of Proposition 13.2.

**Corollary 13.5.** For every $x \in \mathcal{C} \setminus \mathcal{W}^u(\mathcal{B})$ at which $\sigma^h(x)$ exists we have $\sigma^h(x) \leq 1$. Moreover, equality holds at Lebesgue almost every such $x$.

**Proof.** Theorem 8.1 gives that $R$ is horizontally expanding with rate $\lambda = 2$, implying the upper bound. The second statement follows by combining Corollary 11.2 with Proposition 13.4. \qed

**Remark 13.1.** The partial derivative $\chi_T(h) := \partial M(h, T)/\partial h$ is called susceptibility. Kaufman and Griffiths proved in [KG] that the Ising model on DHL exhibits an infinite susceptibility at $h = 0$ for $T \geq T_c$. More precisely, as was shown by Bleher and Žalys [BZ3], the susceptibility $\chi_T(h)$ has a logarithmic singularity at $h = 0$ for $T > T_c$.

14. Periodic Leaves

Let us distinguish between two distinct types of leaves $\gamma \subset \mathcal{F}^c$ that are periodic under $\mathcal{R}$. We say that a periodic leaf $\gamma$ is regular if $\gamma \cap \mathcal{T}$ is a periodic point. If $\gamma$ is a periodic leaf that is not regular, then $\gamma \cap \mathcal{T}$ is in the preindeterminacy set $\mathcal{A}$.

Associated to any periodic point $x_1 \in \mathcal{T}$ is a regular periodic leaf meeting $\mathcal{T}$ at $x_1$. Meanwhile, associated to any periodic point $x_0 \in \mathcal{B}$ there is a periodic leaf meeting $\mathcal{B}$ at $x_0$, which need not be regular—since almost ever point in $\mathcal{B}$ is in the union of the stable tongues, it is quite common to obtain a singular periodic leaf from a periodic $x_0 \in \mathcal{B}$.

The periodic points $x_0$ and $x_1$ at the bottom and top of a regular periodic leaf $\gamma$ are horizontally repelling and vertically (super) attracting. They have real-analytic (super) stable manifolds $\mathcal{W}^s(x_0)$, $\mathcal{W}^s(x_1)$, which extend slightly below $\mathcal{B}$ and above $\mathcal{T}$, respectively. The high-temperature hair $h_\gamma = \mathcal{W}^s(x_1) \cap \mathcal{C}$ and the low-temperature hair $l_\gamma := \mathcal{W}^s(x_0) \cap \mathcal{C}$ are both real-analytic and non-trivial. Therefore, the smoothness of a regular periodic leaf $\gamma$ is determined within its critical points $c_\gamma = \gamma \setminus (h_\gamma \cup l_\gamma)$.

**Proposition 14.1.** Suppose that $\gamma \in \mathcal{F}_c$ is a regular periodic leaf of prime period $k > 1$. Then, $\gamma$ is not real-analytic.

The assumption that $k > 1$ is necessary, since the vertical interval $\mathcal{I}_0$ is a regular periodic leaf of period 1. The assumption that $\gamma$ is a regular periodic leaf is also necessary, because there are many periodic leaves contained entirely within $\mathcal{W}^s(\mathcal{B})$ that are real-analytic.
Proof. We suppose that $\gamma$ is a regular periodic leaf, of prime period $k > 1$, that is real-analytic. Let $x_0$ and $x_1$ be the periodic points at the bottom and top of $\gamma$, respectively. We extend $\gamma$ analytically slightly below $x_0$ and above $x_1$ and then take a complexification $\gamma_C$, chosen sufficiently small so that it is an embedded complex disc.

Let $x_c = \gamma(t^-)$ be the periodic point “at the bottom of $c$.” It has has one-dimensional central direction and one-dimensional unstable direction, with multipliers $1 \leq \lambda_c < \lambda_u$. Any small piece of $\gamma$ containing $x_c$ in its interior will be a central manifold $W^C_{loc}(x_c)$. Similarly, an open disc from $\gamma_C$ containing $x_c$ will form a complex analytic central manifold $W^C_{loc}(x_c)$.

Consider the case that $x_c$ is vertically repelling: $\lambda_c > 1$. Let $\rho_0 : \mathbb{D} \to W^C_{loc}(x_c)$ be a local linearizing coordinate, i.e. $\rho_0(\lambda_c x) = R(\rho_0(x))$. It can be globalized to form a non constant $\rho : \mathbb{C} \to \mathbb{CP}^2$ satisfying $\rho(\lambda_c x) = R^k(\rho(x))$ that is given by

$$\rho(x) := \lim_{n \to \infty} R^{-k}(\rho_0(x/\lambda_c^n)).$$

Suppose $R^l(\rho_0(x_*/\lambda_c^n))$ lands on an indeterminacy point for some $x_* \in \mathbb{C}$. After taking appropriate blow-ups at the indeterminate point, $R$ extends to some holomorphic $\hat{R}$. (See Appendix A.2.) The image under $R^l(\rho_0(x/\lambda_c^n))$ of some complex disc $D$ containing $x_*$ lifts to the blown-up space via the proper transform, intersecting the exceptional divisor in a single point. We define the next iterate on this disc using $\hat{R}$. This definition coincides with $R^{l+1}(\rho_0(x/\lambda_c^n))$ on $D \setminus \{x_*\}$ and gives a holomorphic extension through $x_*$. A global central manifold $W = W^C_{glob}(x_c)$, invariant under $R^k$, is given by $\rho(\mathbb{C})$. A-priori, $W$ can be wild, possibly accumulating on itself. However, we will show that $W$ can be compactified to form an algebraic curve.

Given $x, y \in \mathbb{C}$, let $x \sim y$ if and only if there exist neighborhoods of $N_x$ and $N_y$ of $x$ and $y$ respectively, and a biholomorphism $h : N_x \to N_y$ so that $\rho|_{N_x} = \rho|_{N_y} \circ h$. Then $\hat{W} = \mathbb{C}/\sim$ is a Riemann surface whose charts are obtained by appropriate local sections of the projection $\pi : \mathbb{C} \to \hat{W}$. The map $\hat{\rho} : \hat{W} \to \hat{W}$ that is induced by $\rho$ is holomorphic and provides a nice parameterization of $W$, which is injective on all but a discrete subset of $\hat{W}$.

The action of $R^k : W \to W$ can be lifted (in the natural way) to $\hat{R}^k : \hat{W} \to \hat{W}$. Notice that $\pi(0) \in \hat{W}$ is a repelling fixed point under $\hat{R}^k$ so that $\hat{W}$ is non-hyperbolic.

We construct a larger Riemann surface $V := (\hat{W} \cup \gamma_C)/\hat{\rho}$, where $x \in \hat{W}$ and $y \in \gamma_C$ are identified if and only if $\hat{\rho}(x) = y$ with some neighborhood of $x$ in $\hat{W}$ mapped by $\hat{\rho}$ into $\gamma_C$. The natural inclusion $\iota : \hat{W} \to V$ is holomorphic. Since $V$ is not hyperbolic, $\iota$ can omit at most two points of $V$. Hence $\hat{\rho}$ can omit at most two points of $\gamma_C$. Therefore, we can (at least) choose some punctured discs $U_{0,1} \subset \gamma_C$ in the image of $\hat{\rho}$, having $x_{0,1}$ as their punctures (respectively).

Let $\hat{U}_0 \subset \hat{W}$ be the punctured disc mapped biholomorphically by $\hat{\rho}$ onto $U_0$. Since $\beta_0$ is the only point in $L_0$ having an iterated preimage under $R$ outside of $L_0$, it is the only point that can possibly be in $\mathcal{W} \cap L_0$. By assumption, $x_0 \neq \beta_0$, so there is no point in $\mathcal{W}$ mapping to $x_0$. Thus, the puncture in $\hat{U}_0$ corresponds to an actual puncture in $\mathcal{W}$.

Let $\hat{\mathcal{W}}_0 = \hat{W} \cup \{w_0\}$ be the Riemann surface obtained by filling in this puncture. Both $\hat{\rho}$ and $\hat{R}^k$ extends to $\hat{\mathcal{W}}_0$, with $\hat{\rho}(w_0) = x_0$ and $\hat{R}^k(w_0) = w_0$. 

Since \( \hat{W} \) is non-hyperbolic with at least one puncture, \( \hat{W}_0 \) is biholomorphic to either \( \mathbb{C} \) or \( \mathbb{CP}^1 \). In either case, \( \hat{R}^k : \hat{W}_0 \to \hat{W}_0 \) has a degree. (If \( \hat{W}_0 \cong \mathbb{C} \), the action of \( \hat{R}^k \) is polynomial, since any point has finitely many preimages under \( \hat{R}^k \).)

Since \( w_0 \) is totally invariant under \( \hat{R}^k \), with a neighborhood mapped to itself with degree \( 2^k \), we see that \( \hat{R}^k : \hat{W}_0 \to \hat{W}_0 \) has degree \( 2^k \).

Let \( \hat{U}_1 \subset \hat{W} \) be the punctured disc mapped by \( \hat{\rho} \) biholomorphically onto \( U_1 \). If there were a point \( w_1 \in \hat{W} \) filling the puncture in \( \hat{U}_1 \), it would satisfy \( \hat{\rho}(w_1) = x_1 \), and the local degree of \( \hat{R}^k \) at \( w_1 \) would be \( 2^k \). However, if \( x_1 \in \hat{W} \), there must be iterated preimages of \( x_1 \) under \( \hat{R}^k \) in \( \hat{W} \) converging to \( x_c \), violating that the total degree of \( \hat{R}^k : \hat{W} \to \hat{W} \) is \( 2^k \).

Therefore, the puncture in \( \hat{U}_1 \) corresponds to an actual puncture in \( W \). As before, it can be filled and \( \hat{\rho} \) extends holomorphically to the resulting space.

Since \( \hat{W} \) is non-hyperbolic and has two punctures, it is biholomorphic to the twice punctured Riemann sphere. Since \( \hat{\rho} \) extends holomorphically through both of the punctures, sending each to \( x_0 \) and \( x_1 \), respectively, \( \overline{W} = \hat{W} \cup \{x_0, x_1\} \) is a compact analytic curve. Chow’s Theorem (see, e.g., [GH]) gives that \( \overline{W} \) is therefore algebraic.

One local branch of \( \overline{W} \) at \( x_0 \) is \( W^{\mathbb{C}, \text{loc}}_c(x_0) \). Since it intersects \( L_0 \) perpendicularly, \( \overline{W} \) cannot have degree 1, for it would intersect \( T \) in a point of prime period \( 2k \).

Bézout’s Theorem gives a second intersection of \( \overline{W} \) with \( L_0 \). It corresponds to some disc in \( \hat{W} \), disjoint from \( \hat{U}_0 \), whose image under \( \hat{\rho} \) intersects \( L_0 \). Therefore this intersection must be at \( \beta_0 \). However, \( \overline{W} \) does contain either of the invariant separatrices \( z = 1 \) or \( t = 0 \), so the dynamics near \( \beta_0 \) would result in infinitely many branches, which is impossible.

Suppose that \( x_c \) is vertically neutral. Then, within \( W^{\mathbb{C}, \text{loc}}_c(x_c) \) is some repelling petal \( P \) for the parabolic point \( x_c \). Then there is some open \( H \subset \mathbb{C} \) containing a left half-space with Fatou coordinate \( \rho_0 : H \to P \) a conformal isomorphism that satisfies \( \rho_0(x + 1) = \hat{R}^k(\rho_0(x)) \). We define \( \rho : \mathbb{C} \to \mathbb{CP}^2 \) by

\[
\rho(x) = \lim_{n \to \infty} \hat{R}^n(\rho_0(x - n)).
\]

The composition extends through indeterminate points of \( \hat{R} \) in the same way as in the repelling case.

Then, \( \rho(C) \subset \mathbb{CP}^2 \) is forward invariant under \( \hat{R}^k \) and contains \( P \), which is an open subset of \( \gamma_C \). As in the repelling case, one can compactify \( \rho(C) \) to form a periodic algebraic curve. This again leads to an intersection with \( \beta_0 \), and a contradiction.

\[\square\]

**Remark 14.1.** Artur Avila has shown that for almost all points \( x = (\phi, 1) \) on the top \( T \), the leaf landing at \( x \) is not real analytic.

**Proposition 14.2.** Suppose that \( \gamma \) is a regular periodic leaf (of prime period \( k > 1 \)) containing no vertically neutral periodic points. Then, \( \gamma \) has a finite degree of smoothness.

**Proof.** Let \( \gamma_m = \gamma([0, t_m]) \) be the maximal real-analytic piece of \( \gamma \) extending from \( B \). By Proposition 14.1, \( \gamma_m \subseteq \gamma \), with \( x_m := \gamma(t_m) \) a periodic point of prime period \( k \).
By hypothesis, \( \lambda_c(x_m) \neq 1 \). Furthermore, \( x_m \) cannot be vertically attracting, since the stable manifold \( W^s(x_m) \) would be a real-analytic curve within \( \gamma \) that extends above and below \( x_m \). Therefore, \( x_m \) is vertically repelling.

Suppose that \( x_m \) is linearizable. Then, \( \mathcal{R} \) is conjugate to the linear map \((u, v) \mapsto (\lambda_u u, \lambda_v v)\). Any central invariant manifold has the form

\[
u = \begin{cases} C_1 v^\alpha & \text{if } v \geq 0, \\ C_2 v^\alpha & \text{if } v < 0, \end{cases}
\]

where \( \alpha = \log(\lambda_u)/\log(\lambda_v) \). By the choice of \( x_m \), the central manifold that is formed by \( \gamma \) is not analytic at \( x_m \), therefore it does not correspond to \( C_1 = C_2 = 0 \) or, if \( \alpha \in \mathbb{N} \), to \( C_1 = C_2 \). In the remaining cases, the central manifold is not of class \( C^r \), where \( r - 1 < \alpha \leq r \).

Since \( \lambda_c, \lambda_u > 1 \), we are in the Poincaré domain, with the only obstruction to linearization being a resonance of the form \( \lambda_c^r = \lambda_u \) for some \( r \in \mathbb{N} \). Thus, if \( x_m \) is not linearizable, the Poincaré–Dulac Theorem gives that in some neighborhood \( U \subset \mathcal{C} \) of \( x_c \), \( \mathcal{R} \) is real-analytically conjugate to the normal form

\[
(u, v) \mapsto (\lambda_u u + av^r, \lambda_v v)
\]

with \( a \neq 0 \). (See, e.g., [IY].)

Any central manifold is given by \( u = g(v) \). Invariance gives:

\[
aw^r = g(\lambda_c v) - \lambda_u g(v) = g(\lambda_c v) - \lambda_c^r g(v)
\]

Differentiating \( r \) and \( r + 1 \) times, respectively, one finds

\[
(14.1) \quad ar!/\lambda_c^r = g^{(r)}(\lambda_c v) - g^{(r)}(v), \quad \text{and}
\]

\[
(14.2) \quad 0 = \lambda_c g^{(r+1)}(\lambda_c v) - g^{(r+1)}(v).
\]

By (14.2), either \( g^{(r+1)}(v) \equiv 0 \), or it is undefined at \( v = 0 \). In the former case, substitution of \( g^{(r)}(v) \equiv C \) into (14.1) gives a contradiction. Thus, the central manifold is not of class \( C^{r+1} \).

Since the leaves of \( \mathcal{F}^c \) are obtained by integrating the continuous line field \( \mathcal{L}^c(x) \), they are all at least \( C^1 \) smooth. In fact, the regular periodic leaves have a slightly better smoothness:

**Proposition 14.3.** Any regular periodic leaf \( \gamma \in \mathcal{F}^c \) is \( C^{1+\delta} \) for some \( \delta > 0 \).

**Proof.** It suffices to show that the line field \( \mathcal{L}^c \) is Hölder on \( \gamma \) with exponent \( \delta \).

Replacing \( \mathcal{R} \) with an iterate of itself (keeping the same notation) we can assume that \( \gamma \) is invariant. Below, the inverse map \( \mathcal{R}^{-1} \) will stand for \( (\mathcal{R} \gamma)^{-1} \).

For any \( x, y \in \gamma \) and two parallel tangent lines \( X \in \mathcal{K}^v(x), Y' \in \mathcal{K}^v(y) \) we have a Lipschitz estimate:

\[
\text{dist}_a(\mathcal{DR}^{-1}X, \mathcal{DR}^{-1}Y') \leq M \text{dist}(x, y),
\]

where \( \text{dist}_a \) denotes the angular distance.

On the other hand, Lemma 7.3 implies that there exists \( \sigma \in (0, 1) \) so that for any vertical lines \( L, L' \in \mathcal{K}^v(y) \) we have

\[
\text{dist}_a(\mathcal{DR}^{-1}Y', \mathcal{DR}^{-1}Y) \leq \sigma \text{dist}(Y', Y)
\]

Putting the last two estimates together, we obtain

\[
\text{dist}_a(\mathcal{DR}^{-1}X, \mathcal{DR}^{-1}Y) \leq \sigma \text{dist}_a(X, Y) + M \text{dist}(x, y)
\]
for any $X \in \mathcal{K}^v(x)$, $Y \in \mathcal{K}^v(y)$. Iterating this estimate in the backward time we obtain\textsuperscript{28}:

\begin{equation}
\text{dist}_a(DR^{-n}X, DR^{-n}Y) \leq \frac{Md_n(x,y)}{1 - \sigma}, \quad \text{where } d_n(x,y) = \max_{0 \leq k \leq n-1} \text{dist}(R^{-k}x, R^{-k}y),
\end{equation}
as long as $\text{dist}_a(X, Y) < d/(1 - \sigma)$. (We can always start with parallel $X$ and $Y$).

Let now $K$ be a Lipschitz constant for $R|_{\gamma}$, and let $K_1 \geq K$. Take two nearby points $\alpha, \beta, \in \gamma$ and find $n$ such that

\begin{equation}
K_1^{-n} \leq \text{dist}(\alpha, \beta) < K_1^{-(n-1)}.
\end{equation}

Letting $x = R^n\alpha$, $y = R^n\beta$, we obtain

\begin{equation}
d_n(x,y) \leq K^n d(\alpha, \beta) \leq \kappa^n, \quad \text{where } \kappa = K/K_1 < 1.
\end{equation}

By (14.3), we have

\[ \text{dist}_a(DR^{-n}X, DR^{-n}Y) = O(\kappa^n). \]

But according to Proposition 7.1, $DR^{-n}X$ is exponentially close to the tangent line $L^v(\alpha)$ to $\gamma$ at $\alpha$, and likewise $DR^{-n}Y$ is exponentially close to the tangent line $L^v(\beta)$. Hence

\[ \text{dist}_a(L^v(\alpha), L^v(\beta)) = O(\eta^n) \quad \text{for some } \eta \in (0, 1). \]

Together with (14.4), this implies that

\[ \text{dist}_a(L^v(\alpha), L^v(\beta)) \leq C \text{dist}(\alpha, \beta)^\delta, \quad \text{with } \delta = \frac{\log K_1}{\log(1/\kappa)}. \]

\[ \square \]

**Remark 14.2.** The above argument applies to any vertical leaf whose forward orbit stays away from the points of indeterminacy $\alpha_\pm$. The problem with other leaves is that the Lipschitz estimate for $R|_{\gamma}$ may fail for leaves $\gamma$ passing through $\alpha$ because of the big expansion near the $\alpha_\pm$.

**Appendix A. Elements of complex geometry**

We are primarily interested in rational maps between complex projective spaces in two dimensions. However, in order to understand the behavior near indeterminate points, we will need a discussion at somewhat greater generality. Much of the below material can be found in with greater detail in [Da, De, GH, Shaf].

**A.1. Projective varieties and rational maps.** Let $\pi : \mathbb{C}^{k+1} \setminus \{0\} \to \mathbb{CP}^k$ denote the canonical projection. Given $z \in \mathbb{CP}^k$, any $\hat{z} \in \pi^{-1}(z)$ is called a *lift* of $z$. One calls $V \subset \mathbb{CP}^k$ a (projective) algebraic hypersurface if there is a homogeneous polynomial $\hat{p} : \mathbb{C}^{k+1} \to \mathbb{C}$ so that

\[ V = \{ z \in \mathbb{CP}^k : \hat{p}(\hat{z}) = 0 \}. \]

More generally, a (projective) algebraic variety is the locus satisfying a finite number projective polynomial equations. Any algebraic variety $V$ has the structure of a smooth manifold away from a proper subvariety $V_{\text{sing}} \subset V$ and the dimension of $V \setminus V_{\text{sing}}$ is called the *dimension* of $V$.

\textsuperscript{28}The simplest way to see it is to notice that the iterates are bounded by the fixed point of the linear map $x \mapsto \sigma x + Md$.\hfill \qed
A rational map \( R : \mathbb{CP}^k \to \mathbb{CP}^l \) is given by a homogeneous polynomial map \( \hat{R} : \mathbb{CP}^{k+1} \to \mathbb{CP}^{l+1} \) for which we will assume the components have no common factors. One defines \( R(z) := \pi(\hat{R}(\hat{z})) \) if \( \hat{R}(\hat{z}) \neq 0 \), and otherwise we say that \( z \) is an indeterminacy point for \( R \). Since \( \hat{R} \) is homogeneous, the above notions are well-defined. Because the components of \( \hat{R} \) have no common factors, the set of indeterminate points \( I(R) \) is a projective variety of codimension greater than or equal to two.

Given two projective varieties, \( V \subset \mathbb{CP}^k \) and \( W \subset \mathbb{CP}^l \), a rational map \( R : V \to W \) is the restriction of a rational map \( \hat{R} : \mathbb{CP}^{k+1} \to \mathbb{CP}^{l+1} \) such that \( R(V \setminus I(R)) \subset W \).

As above, \( I(R) \subset V \) is a projective subvariety of codimension greater than or equal to two in \( V \). If \( I(R) = \emptyset \), we say that \( R \) is a (globally) holomorphic (regular) map.

A rational mapping \( R : V \to W \) between non-singular varieties is dominant if there is a point \( z \in V \setminus I(R) \) such that \( \text{rank} DR(z) = \dim W \).

**Lemma A.1.** Let \( R : V \to W \) be a dominant rational map between non-singular varieties. If \( z \) is not an indeterminate point for \( R \), then \( R \) is locally surjective at \( z \).

It is a consequence of the Weierstrass Preparation Theorem—see Propositions 4.8 and 4.19 from [De].

**A.2. Blow-ups.** A non-singular variety of dimension two is called a projective surface. Matters are simpler for maps \( R : V \to W \) between projective surfaces since \( I(R) \) is finite in this case. (We will refer to such maps as “rational surface maps”.)

Given a pointed projective surface \( (V, p) \), the blow-up of \( V \) at \( p \) is another projective surface \( \hat{V} \) with a holomorphic projection \( \pi : \hat{V} \to V \) such that

- \( L_{\text{exc}}(p) := \pi^{-1}(p) \) is a complex line \( \mathbb{CP}^1 \) called the exceptional divisor;
- \( \pi : \hat{V} \setminus L_{\text{exc}}(p) \to V \setminus \{p\} \) is a biholomorphic map.

See [GH, Shaf].

The construction has a local nature near \( p \), so it is sufficient to provide it for \( (\mathbb{C}^2, 0) \). The space of lines \( l \subset \mathbb{C}^2 \) passing through the origin is \( \mathbb{CP}^1 \) by definition. Then \( \mathbb{CP}^1 \) is realized as the surface \( X \subset \mathbb{C}^2 \times \mathbb{CP}^1 \) given by equation \( \{(u, v, l) \in l \} \) with the natural projection \( (u, v, l) \mapsto (u, v) \). In this model, points of the exceptional divisor \( L_{\text{exc}} = \{(0, 0, l) : l \in \mathbb{CP}^1\} \) get interpreted as the directions \( l \) at which the origin is approached.

Any line \( l \subset \mathbb{C}^2 \) naturally lifts to the “line” \( \tilde{l} = \{(u, v, l) : (u, v) \in l\} \) in \( \hat{\mathbb{C}}^2 \) crossing the exceptional divisor at \((0, 0, l)\).\(^{29}\) Moreover, \( \hat{\mathbb{C}}^2 \setminus \tilde{l} \) is isomorphic to \( \mathbb{C}^2 \). Indeed, let \( \phi(u, v) = au + bv \) a linear functional that determines \( l \). It is linearly independent with one of the coordinate functionals, say with \( v \) (so \( a \neq 0 \)). Then

\[
(u, v, l) \mapsto (\phi, \kappa := v/\phi)
\]

is a local chart that provides a desired isomorphism. In particular, two charts corresponding to the coordinate axes in \( \mathbb{C}^2 \) provide us with local coordinates \((u, \kappa = v/u) \) and \((v, \kappa = u/v) \) which are usually used in calculations.

The value of this construction lies in the fact that it can be used to resolve the indeterminacy of a rational map, as follows:

**Theorem A.2** (See [Shaf], Ch. IV, §3.3). Let \( R : V \to W \) be a rational surface map. Then there exists a sequence of blow-ups \( V_m \xrightarrow{\pi_m} \cdots \xrightarrow{\pi_2} V_1 \xrightarrow{\pi_1} V \) so that

\(^{29}\)This turns \( \hat{\mathbb{C}}^2 \) into a line bundle over \( \mathbb{CP}^1 \) known as the tautological line bundle.
$R$ lifts to a globally holomorphic map $\tilde{R} : V_m \to W$ making the following diagram commute\textsuperscript{30}:

$$
\begin{array}{ccc}
V_m & \xrightarrow{\pi} & V \\
\downarrow{\tilde{R}} & & \downarrow{R} \\
\mathbb{CP}^n & & \mathbb{CP}^n.
\end{array}
$$

Here, $\pi = \pi_1 \circ \cdots \circ \pi_m$.

Any analytic curve $D$ on $V$ lifts to an analytic curve $\tilde{D} := \pi^{-1}(D \setminus \{p\})$ on $\tilde{V}$, known as the proper transform of $D$, which tends to have milder singularities than $D$:

**Theorem A.3.** Let $D$ be an irreducible curve on a non-singular projective surface $V$. Then, there exist a sequence of blow-ups $V_m \xrightarrow{\pi_m} \cdots \xrightarrow{\pi_2} V_1 \xrightarrow{\pi_1} V$ so that the proper transform of $\tilde{D}$ of $D$ is a non-singular curve on $V_m$.

See [Shaf, Ch. IV, §4.1].

**A.3. Divisors.** Divisors are a generalization of algebraic hypersurfaces that behave naturally under dominant rational maps. We will present an adaptation of material from [Da, Ch. 3], [F, §3], and [Shaf] suitable for our purposes.

A divisor $D$ on a projective surface $V$ is a collection of irreducible hypersurfaces $C_1, \ldots, C_r$ with assigned integer multiplicities $k_1, \ldots, k_r$. One writes $D$ as a formal sum

$$D = k_1 C_1 + \cdots + k_r C_r. \tag{A.1}$$

Alternatively, $D$ can be described by choosing an open cover $\{U_i\}$ of $V$ and rational functions $g_i : U_i \to \mathbb{C}$ with the comparability property that $g_i/g_j$ is a non-vanishing holomorphic function on $U_i \cap U_j \neq \emptyset$. Taking zeros and poles of the $g_i$ counted with multiplicities, we obtain representation (A.1).

These two equivalent descriptions of divisors allow us to pull them back and push them forward under rational maps: If $f : V \to W$ is a dominant holomorphic map, and $D = \{U_i, g_i\}$ is a divisor on $W$. The pullback $f^* D$ is the divisor on $V$ given by $\{f^{-1} U_i, f^* g_i\} \equiv \{f^{-1} U_i, g_i \circ f\}$.

If $f : V \to W$ is a proper holomorphic map and $D$ is an irreducible curve on $V$ we define its push-forward $f_* D$ to be the divisor that assigns multiplicity\textsuperscript{31} $\deg_{\text{top}}(f|V) : V \to W$ to the image curve $f(V)$. (If $f$ collapses $V$ to a point, we assign multiplicity 0.) This definition extends linearly to arbitrary divisors on $V$ expressed in form (A.1).

If $R : V \to W$ is a rational map having indeterminacy, we use Theorem A.2 to define the pull-back and push forward of divisors by

$$R^* D_1 := \pi_* \tilde{R}^* D_1 \quad R_* D_2 := \tilde{R}^* \pi_* D_2 \tag{A.2}$$

where $D_1$ and $D_2$ are divisors on $W$ and $V$, respectively.

Alternatively, one can pull-back $D$ under $R : V \setminus I(R) \to W$. Since $I(R)$ is a finite collection of points, the result (in terms of local defining functions) can be

\textsuperscript{30}As with diagram (3.1), commutativity is only at points where all maps are defined.

\textsuperscript{31}Note that it is possible for a non-generic point of $f(V)$ to have more than $\deg_{\text{top}}(f : V \to W)$ preimages under $f|V$. 

extended trivially to obtain a divisor $R^*D$ on all of $V$. Since the trivial extension of a divisor is unique, this alternative definition agrees with the previous one.

Any hypersurface $C$ can be triangulated as a singular cycle, thus to any divisor $D$ is an associated fundamental class $[D] \in H_2(V)$. Representing $D$ by local defining functions allows us to associate a cohomology class $(D) \in H^2(V)$ called its Chern class; see [F]. Furthermore, $[D]$ is the Poincaré dual of $(D)$.

These classes are natural satisfying $[f_*D_1] = f_*[D_1]$ and $(f^*D_2) = f^*(D_2)$ for any holomorphic map $f : V \to W$. For a rational map $R : V \to W$, we again have

$$[R_*D_1] = R_*[D_1] \text{ and } (R^*D_2) = R^*D_2,$$

using (A.2) at the level of homology and cohomology and also Poincaré duality.

A4. Composition of rational maps. The algebraic degree of a rational map $R : \mathbb{P}^k \to \mathbb{P}^l$, denoted $\deg R$, is the degree of the coordinates of its lift $\hat{R} : \mathbb{C}^{k+1} \to \mathbb{C}^{l+1}$.

The following statement appears in [Si, Prop. 1.4.3]:

Lemma A.4. Let $R : \mathbb{P}^k \to \mathbb{P}^l$ and $S : \mathbb{P}^l \to \mathbb{P}^m$ be rational maps. Then, $\deg(S \circ R) = \deg(S) \cdot \deg(R)$ if and only if there is no algebraic hypersurface $V \subset \mathbb{P}^m$ that is collapsed by $R$ to an indeterminate point of $S$.

Proof. Let $\hat{R}$ and $\hat{S}$ be lifts of $R$ and $S$ of degree $\deg R$ and $\deg S$, respectively. An irreducible algebraic hypersurface $V$ given by $\{p(z) = 0\}$ (where $p$ is prime) is collapsed under $R$ to an indeterminate point for $S$ if and only if $p(\hat{z})$ divides each of the components of $\hat{S} \circ \hat{R}$. On the other hand, $\hat{S} \circ \hat{R}$ has a common factor if and only if $\deg(S \circ R) < \deg S \cdot \deg R$. \hfill $\square$

Remark A1. To understand this phenomenon geometrically (for simplicity, in dimension two: $k = l = m = 2$), let us consider the algebraic curve $G$ to which the indeterminacy point $\gamma$ blows up under $S$. Then any line $L$ must intersect $G$, and hence $S^{-1}(L \setminus \gamma)$. It follows that $V \subset \mathbb{C}^{k+1} \setminus (S^{-1}L)$. On the other hand, $V \not\subset (S \circ R)^{-1}L$ (unless $L \supset G$, which may happen only for a special line). But according to Lemma A.5 below,

$$\deg S \cdot \deg R = \deg(S^{-1}(R^{-1}L)), \quad \deg(S \circ R) = \deg(S \circ R)^{-1}L$$

So, components of $V$, possibly with multiplicities, account for the degree deficit.

A5. Degree of divisors in $\mathbb{P}^2$. Associated to any homogeneous polynomial $p : \mathbb{C}^3 \to \mathbb{C}$ is a divisor $D_p$ given by $\{U_i : p \circ \sigma_i\}$, where the $\{U_i\}$ form an open covering of $\mathbb{C}^2$ that admits local sections $\sigma_i : U_i \to \mathbb{C}^3 \setminus \{0\}$ of the canonical projection $\pi$. Furthermore, every divisor can be described as a difference $D = D_p - D_q$ for appropriate $p$ and $q$. The following simple formula describes the pull-back:

$$(A.4) \quad R^*D_p = D_{R^*p} \equiv D_{p \circ R}$$

The degree of a divisor $D = D_p - D_q$ is $\deg D = \deg p - \deg q$. Any complex projective line $L$ on which $p$ does not identically vanish intersects the divisor $D_p$ exactly $\deg D_p$ times (counted with multiplicity), providing an alternative geometric definition of $\deg D_p$.

More generally, Bezout’s Theorem asserts that two divisors $D_1$ and $D_2$ intersect $\deg D_1 \cdot \deg D_2$ times in $\mathbb{P}^2$, counted with appropriate intersection multiplicities.

Suppose that $D_1$ and $D_2$ are irreducible algebraic curves assigned multiplicity one.
Then, an intersection point $z$ is assigned multiplicity one if and only if both curves are non-singular at $z$, meeting transversally there. See [Shaf, Ch. IV].

There is an alternative, homological, definition for $\deg D$. Namely, any algebraic curve $D$ represents a class $[D] \in H_2(\mathbb{C}P^2)$. Moreover, $H_2(\mathbb{C}P^2) = \mathbb{Z}$ and is generated by the class $[L]$ of any line $L$. Then we have

$$[D] = \deg D \cdot [L]$$

**Lemma A.5.** Given a dominant rational map $R : \mathbb{C}P^2 \to \mathbb{C}P^2$ and any divisor $D$ on $\mathbb{C}P^2$ we have:

\[
\deg(R^*D) = \deg R \cdot \deg D, \quad \text{and} \quad \deg(R_*D) = \deg R \cdot \deg D.
\]

In particular, $\deg(R^*L) = \deg(R_*L) = \deg R$ for any projective line $L \subset \mathbb{C}P^2$.

**Proof.** Equation (A.6) follows immediately from (A.4). To obtain (A.7) we make use of the homological interpretation of degree (A.5). By (A.3), the push-forward of divisors $R_*$ preserves homology, so it suffices to check (A.7) for any complex projective line $L$.

We choose $L$ disjoint from $I(R)$ and we can assume that $[0 : 0 : 1] \not\in R(L)$. Let $\iota : \mathbb{C}P^1 \to \mathbb{C}P^2$ be the inclusion of $L$ into $\mathbb{C}P^2$ and $pr : \mathbb{C}P^2 \to \mathbb{C}P^1$ the central projection onto the line at infinity $L_\infty$ from the center $[0 : 0 : 1]$. Note that both $i_{\iota}$ and $R_*$ induce isomorphisms on the second homology.

We consider the composition $pr \circ R \circ \iota : \mathbb{C}P^1 \to \mathbb{C}P^1$. By Lemma A.4,

$$\deg(pr \circ R \circ \iota) = \deg pr \cdot \deg R \cdot \deg \iota = \deg R,$$

since the image of $\iota$ avoids $I(R)$ and the image of $R \circ \iota$ avoids $I(pr) = \{[0 : 0 : 1]\}$.

Thus,

$$pr_* \circ R_*[L] = pr_* \circ R_* \circ \iota_*[\mathbb{C}P^1] = \deg(pr \circ R \circ \iota)[\mathbb{C}P^1] = \deg R \cdot [\mathbb{C}P^1]$$

Since $pr_* : H_2(\mathbb{C}P^2) \to H_2(\mathbb{C}P^1)$ is an isomorphism we find $[R_*L] = \deg R \cdot [L_\infty]$.  

**Remark A.2.** Formulas (A.6) and (A.7) generalize to other varieties using the fact that pull-back and pull-forward (under suitable maps) preserve linear equivalence of divisors, see [Da, Ch. 3 §5.2] and [F, §3.3].

**A.6. Iteration of rational maps.** A rational mapping $R : \mathbb{C}P^2 \to \mathbb{C}P^2$ is called algebraically stable if there is no integer $n$ and no collapsing hypersurface $V \subset \mathbb{C}P^2$ so that $R^n(V)$ is contained within the indeterminacy set of $R$, [Si, p. 109]. By Lemma A.4, $R$ is algebraically stable if and only if $\deg R^n = (\deg R)^n$. Together with Lemma A.5, this yields:

**Lemma A.6.** If $R$ is an algebraically stable map and $D$ is any divisor on $\mathbb{C}P^2$ we have:

\[
\deg((R^n)^*D) = (\deg R)^n \cdot \deg D \\
\deg((R^n)_*D) = (\deg R)^n \cdot \deg D
\]

**Appendix B. Renormalization near the indeterminacy points**

**B.1. Blow-ups.** Below we calculate blow-ups for the renormalization in the affine coordinates $(u, v)$ and in the angular coordinates $(\phi, t)$. 

B.1.1. Affine coordinates. Let us represent $R$ as $Q \circ g$ where

$$g: (u, w) \mapsto \left( \frac{u^2 + 1}{u + w}, \frac{w^2 + 1}{u + w} \right)$$

and $Q: (u, w) \mapsto (u^2, w^2)$. The indeterminacy points for $R$ and $g$ are the same, $a_\pm = \pm (i, -i)$. Because of the basic symmetry $(u, w) \mapsto (w, u)$, it is sufficient to carry the calculation at $a_+ = (i, -i)$. In coordinates $\xi = u-i$ and $\chi = (w+i)/(u-i)$, we obtain the following expression for the map $\tilde{g}: \mathbb{CP}^2 \to \mathbb{CP}^2$ near $L_{\text{exc}}(a_+)$:

$$u = \frac{\xi + 2i}{1 + \chi}, \quad w = \frac{\chi^2 - 2i\chi}{1 + \chi}.$$  \hspace{1cm} \text{(B.1)}

So $L_{\text{exc}}(a_+) = \{\xi = 0\}$ is mapped by $\tilde{g}$ biholomorphically onto the line

$$\{ u = \frac{2i}{1 + \chi}, \quad w = -\frac{2i\chi}{1 + \chi} \} = \{ u - w = 2i \}. \hspace{1cm} \text{(B.2)}$$

In other words, $g$ blows up the indeterminacy point $a_+$ to line (B.2). Notice that this line connects $a_+$ to the low-temperature fixed point $b_0 = (1 : 0 : 1)$ at infinity. Its slice by the Hermitian plane $C = \{ w = \bar{u} \}$ (corresponding to the cylinder $\mathcal{C}$) is the horizontal line $\{ \text{Im} u = 1 \}$.

The lift $\tilde{R}$ of $R$ to $L_{\text{exc}}(a_+)$ is given by $\tilde{R} = Q \circ \tilde{g}$, and hence obtained by squaring the expressions for $u$ and $w$ in (B.1).

B.1.2. Angular coordinates. (compare [BZ3, p. 419]). We will now calculate the blow-up of $\mathcal{R}$ at the indeterminacy points $a_{\pm}$ in the angular coordinates $(\phi, t)$ on $C$. As before, it suffices to consider $a_+$. We let $\epsilon = \frac{\pi}{2} - \phi$ and $\tau = 1 - t$, and $\kappa = \epsilon/\tau$. In the blow-up coordinates $(\epsilon, \kappa)$ we find:

$$\left( z', t' \right) = \left( \frac{-i + \kappa - \epsilon - \epsilon\kappa^2/2}{i + \kappa - \epsilon - \epsilon\kappa^2/2}, \frac{1 - 2\epsilon\kappa}{1 + \kappa^2 - \epsilon(2\kappa + \kappa^3)} \right) + O(|\epsilon|^2), \hspace{1cm} \text{(B.3)}$$

where the constant in the residual term depends on an upper bound on $\kappa$.

Thus

$$\phi' = -i \log(z') = -2 \arccotg(\kappa - \epsilon + \epsilon\kappa^2/2) + O(|\epsilon|^2). \hspace{1cm} \text{(B.4)}$$

Taking the limit as $\epsilon \to 0$, we find:

$$\left( \phi', t' \right) = \left( -2 \arccotg \kappa, \frac{1}{1 + \kappa^2} \right). \hspace{1cm} \text{(B.5)}$$

Letting $\omega$ be the (complexified) angle between the collapsing line $\mathcal{I}_{\pi/2}$ and the line with slope $\kappa = -\cot \omega$, we come up with expression (3.4) for the blow-up locus $\mathcal{Q}$. (Notice that the blow-up loci for the maps $f$ and $\mathcal{R} = f \circ Q$ coincide, since $Q$ is a local diffeomorphism.)

Recall that point $\alpha = (\pi, 1)$, which mapped by $\mathcal{R}$ to the high temperature fixed point $\beta_1$.

**Lemma B.1.** Let $c > 0$. If $\zeta = (\epsilon, \tau) \in \mathbb{C}^2$ is sufficiently close to one of the indeterminacy points $a_{\pm}$ with the slope $\kappa = \tau/\epsilon$ sufficiently small and $|\epsilon - \kappa| \geq c|\epsilon|$, then

$$\text{dist}^h(\mathcal{R}(x), \alpha) \asymp |\epsilon - \kappa|,$$

with the constant depending on $c$.

**Proof.** Indeed, under our assumptions, formula (B.4) implies $|\phi' - \pi| \asymp |\kappa - \epsilon|$. \qed
B.2. The differential $DR$. Formula (3.6) implies the following explicit expression for the differential $DR$ at $x = (\phi, t) \in C$:

\[
DR = \frac{4}{\xi^2} \begin{pmatrix}
\zeta & 0 \\
0 & 1 - t^2
\end{pmatrix} \begin{pmatrix}
1 + t^2 \cos 2\phi & -\sin 2\phi \\
-\tau^2(1 - \tau^2) \sin 2\phi & (1 + t^2)(1 + \cos 2\phi)
\end{pmatrix} \begin{pmatrix}
1 & 0 \\
0 & t
\end{pmatrix}
\]

where $\zeta(x) = 1 + 2t^2 \cos 2\phi + t^4$.

Expanding it in $\tau = 1 - t$ near $T$, we obtain:

\[
DR = \left( \begin{array}{cc}
\frac{2}{\tau^2} & -2 \tau \phi \cos \phi \\
-\tau^2 \phi \cos \phi & -\tau^2 \phi \cos \phi
\end{array} \right) (I + O(\tau))
\]

In the $\epsilon = \pm \pi/2 - \phi$ coordinate near an indeterminacy point $\alpha_{\pm}$ we obtain the following asymptotic expression for the differential $R : (\epsilon, \tau) \mapsto (\phi', \tau')$:

\[
DR \sim \frac{2}{\sigma^2} \begin{pmatrix}
(\epsilon^2 + \tau) \sigma^2 & -\epsilon \sigma^2 \\
-\epsilon \sigma^2 & \tau \sigma^2
\end{pmatrix}
\]

where $\sigma = \sqrt{\epsilon^2 + \tau^2}$.

B.3. Horizontal stretching near $T$. Let us define the horizontal expansion factor $\lambda^h_{\min}(x)$ at $x \in C \setminus \{\alpha_{\pm}\}$ as

\[
\lambda^h_{\min}(x) = \inf_{v \in K^h(x)} \frac{\pi(DR(v))}{\pi(v)}.
\]

Equivalently, consider an almost horizontal curve $\xi$ through $x = (\phi, t)$ naturally parameterized by the angular coordinate (by means of $(\pi|\xi)^{-1}$). Let

\[
\chi \equiv \chi_\xi = \pi \circ R \circ (\pi|\xi)^{-1}.
\]

Then

\[
\lambda^h_{\min}(x) = \inf_{\xi} \chi'(\phi).
\]

The $n$-th horizontal expansion factor $\lambda^h_{\min,n}(x)$ is defined similarly, by replacing $DR$ with $DR^n$ in (B.9).

Lemma B.2. There exists $\lambda_0 > 0$ so that for any $x = (\epsilon, \tau) \in C \setminus \{\alpha_{\pm}\}$ near one of the indeterminacy points $\alpha_{\pm}$ we have $\lambda^h_{\min}(x) \geq \lambda_0$.

Moreover, given a slope $\kappa > 0$, there exits $\lambda_1 > 0$ such that if $x = (\epsilon, \tau)$ also satisfies $|\kappa| \equiv |\tau/\epsilon| \leq \kappa$, then

\[
\lambda^h_{\min}(x) \geq \lambda_1 \left| \frac{\kappa}{\epsilon} \right|.
\]

Proof. Take a horizontal vector $v = (1, s) \in K^h(x)$ with slope $s$. By definition of the horizontal cone field $K^h$, $|s| \leq \max\{\sqrt{2}\kappa, |\epsilon|/3\}$ (see §6.2, items (iii)-(iv) in the definition of $K^h$). Applying the asymptotical expression (B.8), we obtain

\[
\chi'(\phi) = \pi(DR(1, s)) = \frac{2\epsilon^2 + \tau - s\epsilon}{|\sigma|^2}
\]

\[
\geq \frac{2}{|\sigma|^2} \min\{\epsilon^2 + \tau - |\epsilon|\sqrt{2}\kappa, (2/3)|\epsilon|^2 + \tau\} \geq \lambda_0 \frac{\epsilon^2 + \tau}{|\epsilon|^2 + \tau^2} \geq \lambda_0.
\]
The second to last estimate follows from positive definitiveness of the quadratic form \( \epsilon^2 + \tau - \epsilon \sqrt{2\tau} \) in \( \epsilon \) and \( \sqrt{\tau} \). Finally,

\[
\frac{\epsilon^2 + \tau}{\epsilon^2 + \tau^2} = \frac{|\kappa + \epsilon|}{\epsilon(|\kappa^2 + 1)} \geq \frac{1}{\kappa^2 + 1} \frac{|\kappa + \epsilon|}{\epsilon},
\]

and the second estimate follows. \( \square \)

**Lemma B.3.** There exists \( \lambda_2 > 0 \) so that for any \( x \in C \setminus \{ \alpha_\pm \} \) we have \( \lambda_{\text{min}}^h(x) \geq \lambda_2 \).

**Proof.** Away from \( \{ \alpha_\pm \} \) this is true since the horizontal cones are transverse to the critical lines \( I_{\pm \pi/2} \). Near \( \{ \alpha_\pm \} \), it follows from Lemma B.2. \( \square \)

We now estimate horizontal expansion of vectors (and hence curves) taken with respect to the algebraic cone field \( \mathcal{K}^{ah} \). It will be useful to consider both upper and lower bounds:

\[
\lambda_{\text{min}}^h(x) = \inf_{v \in \mathcal{K}^{ah}(x)} \frac{\pi(D\mathcal{R}(v))}{\pi(v)}, \quad \text{and} \quad \lambda_{\text{max}}^h(x) = \sup_{v \in \mathcal{K}^{ah}(x)} \frac{\pi(D\mathcal{R}(v))}{\pi(v)}
\]

The \( n \)-th expansion factors \( \lambda_{\text{min},n}^h(x) \) and \( \lambda_{\text{max},n}^h(x) \) are defined similarly. Note that \( \lambda_{\text{min}}^h(x) \geq \lambda_{\text{min},n}^h(x) \), since \( \mathcal{K}^{ah}(x) \subset \mathcal{K}^h(x) \). In particular the estimate of Lemma B.2 also applies to \( \lambda_{\text{min}}^h(x) \).

**Lemma B.4.** For any \( \delta > 0 \) there exist \( \eta > 0 \) and \( \tilde{\tau} > 0 \) such that for any \( x \in \mathcal{V}' \) we have:

\[
(2 - \delta) < \lambda_{\text{min}}^h(x) < \lambda_{\text{max}}^h(x) < (2 + \delta).
\]

**Proof.** The slope a vector \( v \in \mathcal{K}^{ah}(x) \) is bounded by \( a \sqrt{\tau} \), where \( a = 1.45 \) and \( \tau = \tau(x) \).

Near the indeterminacy points \( \alpha_\pm \) we can use (B.8) to bound from below the horizontal stretching of the boundary tangent vector \( v = (1, \pm a \sqrt{\tau}) \):

\[
2 \frac{\epsilon^2 + \tau - a|\epsilon|\sqrt{\tau}}{\epsilon^2 + \tau^2} < \pi(D\mathcal{R}(1, s)) < 2 \frac{\epsilon^2 + \tau + a|\epsilon|\sqrt{\tau}}{\epsilon^2 + \tau^2}.
\]

Since \( x \in \mathcal{V}' \), we have \( \sqrt{\tau} < \sqrt{\eta}|\epsilon| \) which gives:

\[
(1 - a \sqrt{\eta})(\epsilon^2 + \tau) \leq \epsilon^2 + \tau \pm a|\epsilon|\sqrt{\tau} \leq (1 + a \sqrt{\eta})(\epsilon^2 + \tau).
\]

Hence

\[
2(1 - a \sqrt{\eta}) \leq \pi(D\mathcal{R}(1, s)) \leq 2(1 + a \sqrt{\eta}),
\]

which can be made arbitrary close to 2 if one’s \( \eta \) is chosen sufficiently small.

Now suppose that \( v \) is based \( \bar{\epsilon} \)-away from \( \alpha_\pm \). Then \( \tan \phi \leq 2/\bar{\epsilon} \) and (B.7) implies:

\[
2(1 - 2\sqrt{\tau/\bar{\epsilon}})(1 + O(\tau)) \leq \pi(D\mathcal{R}(1, s)) \leq 2(1 + 2\sqrt{\tau/\bar{\epsilon}})(1 + O(\tau)),
\]

which can be made arbitrary close to 2 by choosing \( \tau \) small enough. \( \square \)
Appendix C. Complex extension of the cone fields

C.1. Terminology and notation. Let \( \mathcal{C}^c := (\mathbb{C}/2\pi) \times \mathbb{C} \) be the complexification of the full cylinder \( (\mathbb{R}/2\pi) \times \mathbb{R} \).

A real horizontal cone field over \( \mathcal{C} \) is given as

\[
\mathcal{K}(x) = \{ v = (dt,d\phi) \in T_x \mathcal{C} : |dt| < s(x)|d\phi| \} \subset T_x \mathcal{C}
\]

for an appropriate slope function \( s(x) \geq 0 \).

The cones \( \mathcal{K}(x) \) can be complexified to the complex cones \( \mathcal{K}^c(x) \subset T_x \mathcal{C}^c \) by means of the same formula (C.1) where \( dt \) and \( d\phi \) are interpreted as complex coordinates in \( T_x \mathcal{C} \). Notice that \( \mathcal{K}^c(x) \) is obtained by rotating \( \mathcal{K}(x) \) by multiplications \( v \mapsto e^{i\theta}v \). Since \( R \) commutes with this action, invariance of a real cone field \( \mathcal{K}(x) \) implies invariance of its complexification.

So, let us complexify the cone field \( \mathcal{K}^{ah}(x) \) (for \( x \in \mathcal{C} \)). (We will typically omit the superscripts \( c \) from the complexification, to simplify the notation.) We can further extend this cone field to a neighborhood of \( \mathcal{C} \) in \( \mathcal{C}^c \) by extending continuously the slope function \( s \). By continuity, the extension of \( \mathcal{K}^{ah} \) is invariant away from the top. However, for the application to distortion control in §11, we will need an extension that is invariant on a suitable “pinched” neighborhoods of the \( \alpha_\pm \).

C.2. Complex extension of \( \mathcal{K}^{ah} \). Define an extension of \( \mathcal{K}^{ah} \equiv \mathcal{K}^{ah,c} \) to \( \mathcal{C}^c \) by letting \( s^c(\zeta) = \sqrt{1-t^2} = \sqrt{\tau(2-\tau)} \) (compare with (6.3)). For \( \rho > 0 \), let

\[
\mathcal{C}_\rho^c := \{ (\phi,t) \in \mathcal{C}^c : |\text{Im } \phi| < \rho, -\rho < \text{Re } t < 1 + \rho, \text{ and } |\text{Im } t| < \rho \}.
\]

To ensure invariance of the cone field \( \mathcal{K}^{ah} \), we will need to appropriately “pinch” \( \mathcal{C}^c \) near the points of indeterminacy \( \alpha_\pm \). Given \( \theta > 0 \), let

\[
\mathcal{N}(\theta) := \{ (\epsilon, \tau) : |\arg \epsilon \mod \pi| < \theta \text{ and } |\arg \tau \mod 2\pi| < \theta \} \cup \{ |\epsilon| < \frac{1}{2}|\tau| \}.
\]

(Note that in the first set, \( \epsilon \) is allowed to be negative, while \( \tau \) is not.) Furthermore, let

\[
\mathcal{C}_\rho^c(\theta) := \{ \zeta = (\epsilon, \tau) \in \mathcal{C}_\rho^c : \zeta \in \mathcal{N}(\theta) \text{ whenever } |\epsilon| < \rho \text{ and } |\tau| < \rho \}.
\]

Proposition C.1. There exist \( \rho > 0 \) and \( \theta > 0 \) sufficiently small so that if \( \zeta \in \mathcal{C}_\rho^c(\theta) \) then

\[
DR(\mathcal{K}^{ah}(\zeta)) \subset \mathcal{K}^{ah}(R\zeta).
\]

Proof. Since \( \mathcal{K}^{ah}(x) \) is invariant on the real cylinder \( \mathcal{C} \) and non-degenerate on any \( K \in \mathcal{C}_1 \), the extension is invariant on a complex neighborhood of \( K \). Thus, we need only find \( \rho > 0 \) and \( \theta > 0 \) sufficiently small so that (C.3) holds at points in \( \mathcal{C}_\rho^c(\theta) \) with \( |\tau| < \rho \).

For \( c \) slightly above \( \sqrt{2} \), consider the following auxiliary complex cone field

\[
\tilde{K}(\zeta) = \{ v = (dt,d\phi) \in T_x \mathcal{C}^c : |dt| < c\sqrt{|\tau||d\phi|} \} \subset T_x \mathcal{C}^c.
\]

If \( \rho > 0 \) is sufficiently small, then we have \( \mathcal{K}^{ah}(\zeta) \subset \tilde{K}(\zeta) \) for all \( \zeta \in \mathcal{C}^c \). Hence it is sufficient to verify that if \( \zeta \in \mathcal{C}_\rho^c(\theta) \) with \( |\tau(\zeta)| < \rho \), then we have \( R(\tilde{K}(\zeta)) \subset \mathcal{K}^{ah}(R\zeta) \). It will be shown in Lemmas C.2 and C.3 below. By symmetry, it suffices to work near \( \alpha_+ \).
Lemma C.2 (Invariance near $\alpha_\pm$). There exist $\rho > 0$ and $\theta > 0$ with the following property. For any point $\zeta = (\frac{r}{2} - \epsilon, 1 - \tau)$ with $|\tau| < \rho$ and $|\epsilon| < \rho$ lying in the pinched neighborhood $\mathcal{N}(\theta)$ of $\alpha_+$ we have: $\mathcal{D}\mathcal{R}(\hat{\mathcal{K}}(\zeta)) \in \mathcal{K}^{\alpha h}(\mathcal{R}\zeta)$.

Proof. According to the blow-up formula (B.5), if $\rho$ is sufficiently small then $\zeta$ is mapped by $\mathcal{R}$ to a point with $\tau' \approx \frac{\kappa^2}{1 + \kappa^2}$, where $\kappa = \tau/\epsilon$.

Let $v = (1, s)$ be a complex tangent vector based at $(\tau, \epsilon)$ with $v \in \text{cl}(\hat{\mathcal{K}}(\zeta))$, i.e., $|s| \leq c\sqrt{|\tau|}$. We want to show that the slope $s'$ of the image vector $\mathcal{D}\mathcal{R}(v)$ satisfies

$$|s'| < \sqrt{|\tau'(2 - \tau')|} \approx \frac{|\kappa|}{|1 + \kappa^2|} \sqrt{|2 + \kappa^2|}.$$ 

Equation (B.8) from the Appendix B gives us the matrix $A := \frac{(\epsilon^2 - s^2)}{2} \mathcal{D}\mathcal{R}$ to lowest order terms in $\epsilon$ and $\tau$:

$$Av = \begin{pmatrix} (\tau + \epsilon^2 - se)(\tau^2 + \epsilon^2) \\ -\epsilon^2 \tau + se^2 \tau \end{pmatrix}$$

Thus

$$s' \approx \frac{\epsilon \tau (se - \tau)}{(\tau^2 + \epsilon^2)(\tau^2 + \epsilon^2 - se)} = \frac{|\kappa|}{|1 + \kappa^2|} \frac{se - \tau}{\tau + \epsilon^2 - se}$$

so that $\mathcal{D}\mathcal{R}(\hat{\mathcal{K}}(\zeta)) \in \mathcal{K}^{\alpha h}(\mathcal{R}\zeta)$ is equivalent to:

$$\left| \frac{se - \tau}{\tau + \epsilon^2 - se} \right| < \sqrt{2 + \kappa^2} \text{ whenever } |s| \leq c\sqrt{|\tau|}.$$ 

The condition $(\epsilon, \tau) \in \mathcal{N}(\theta)$ with $\theta$ sufficiently small implies $\sqrt{2} \leq \sqrt{2 + \kappa^2}$, so it suffices to show that

(C.5) \[ \left| \frac{se - \tau}{\tau + \epsilon^2 - se} \right| < \sqrt{2} \text{ whenever } |s| \leq c\sqrt{|\tau|}. \]

Because $\mathcal{D}\mathcal{R}$ maps cones to cones, we need only check that the boundary of $\hat{\mathcal{K}}(\zeta)$ is mapped into $\mathcal{K}^{\alpha h}(\mathcal{R}\zeta)$. Thus, we substitute $s = e^{i\theta}c\sqrt{|\tau|}$ into (C.5) obtaining:

(C.6) \[ |e^{i\theta}c\sqrt{|\tau|}\epsilon - \tau| < \sqrt{2} |\tau + \epsilon^2 - e^{i\theta}c\sqrt{|\tau|}\epsilon| \text{ for all } \theta \in \mathbb{R}/2\pi\mathbb{Z}. \]

For real $\epsilon, \tau > 0$, and $\theta = 0$, this inequality is equivalent to postivity of a certain quadratic forms in $(\epsilon, \sqrt{\tau})$, which is straightforward to check.

For complex variables, let us square both sides:

$$|\tau|^2 - 2c\sqrt{|\tau|} \text{Re}(e^{i\theta}\tau) + c^2|\epsilon|^2 + 4\text{Re}(\tau\tau^2) - 4c\sqrt{|\tau|}|\epsilon|^2 \text{Re}(e^{i\theta}\tau) + 2|\epsilon|^4 > 0.$$ 

The hypothesis $(\epsilon, \tau) \in \mathcal{N}(\theta)$ with $\theta$ sufficiently small gives $4\text{Re}(\tau\tau^2) > \gamma |\tau||\epsilon|^2$, where $\gamma < 4$ is arbitrary close to 4. The other two terms with real parts we can replace with absolute values obtaining:

$$|\tau|^2 - 2c|\tau|^{3/2}|\epsilon| + (c^2 + \gamma)|\tau||\epsilon|^2 - 4c|\tau|^{1/2}|\epsilon|^3 + 2|\epsilon|^4 > 0$$

In the variables $u = |\tau|^{1/2}$ and $v = |\epsilon|$, this reduces to positivity of the real quartic form

(C.7) \[ u^4 - 2cu^3v + (c^2 + \gamma)u^2v^2 - 4cuv^3 + 2v^4 > 0. \]

Notice that this inequality with $\gamma = 4$ is equivalent to (C.6) for real $\epsilon, \tau > 0$, and $\theta = 0$. Hence (C.7) is valid for $\gamma = 4$, and by continuity, it is also valid for $\gamma$ close to 4.
Lemma C.3 (Invariance away from $\alpha_{\pm}$). There exist $\rho > 0$ and $\tilde{\tau} > 0$ such that for any $\zeta = (\phi, 1 - \tau)$ with $|\tau| < \tilde{\tau}$ and $|\phi \pm \frac{\tau}{2}| \geq \rho$ we have $D\mathcal{R}(\hat{\mathcal{K}}(\zeta)) \subset \mathcal{K}^{ah}(\mathcal{R}\zeta)$.

Proof. We select $\rho > 0$ as in Lemma C.2. Then for $|\phi \pm \frac{\tau}{2}| \geq \rho$ formula (B.7) implies

$$D\mathcal{R} = \left( \frac{2}{O(\tau^2)} \frac{O(1)}{O(\tau)} \right) (I + O(\tau)),$$

with the coefficients depending on $\rho$. Applied to a tangent vector $v = (1, s) \in T_{\mathcal{C}}C$ with $|s| = c\sqrt{|\tau|}$ we find that $D\mathcal{R}(v)$ has slope $|s'| = O(|\tau|^{3/2}) = o(|\tau|) = o(\sqrt{|\tau|})$, which is less than $\sqrt{|\tau'(2 - \tau')|}$ for $\tau$ (and hence $\tau'$) sufficiently small.

Lemmas C.2 and C.3 complete to proof of Proposition C.1. □

C.3. Stretching of horizontal holomorphic curves. We now consider how holomorphic curves $\xi$ that are horizontal with respect to $\mathcal{K}^{ah}$ are stretched under $\mathcal{R}$.

Let $\pi(z, t) = z$. If $\xi$ is a horizontal holomorphic curve with $\pi(\xi)$ a round disc $D(z, r)$ centered at $z$, we will say that $r^h(\xi, x) = r$. More generally, we let $r^h_{\min}(\xi, x)$ stand for the supremum of the radii of the disks $D(z, r)$ centered at $z$ that can be inscribed into $\pi(\xi) \subset \mathcal{C}$ and $r^h_{\max}(\xi, x)$ the infimum of the discs $D(z, r)$ that can be circumscribed about $\pi(\xi)$. They measure the “horizontal size” of $\xi$ at $x$.

Proposition C.4. Fix any $\bar{\kappa} > 0$. There is a $C > 0$ so that for any sufficiently small $\alpha > 0$ and any $x \in \mathcal{C} \setminus \{\alpha_{\pm}\}$ sufficiently close to $\alpha_{\pm}$ and satisfying $|\kappa(x)| \leq \bar{\kappa}$, there is an iterate $N \equiv N(x)$ so that, if $\xi$ is any horizontal holomorphic curve based at $x$ with

$$r^h(\xi, x) = a|\kappa(x)|,$$

then the subdisc $\xi_0 \subset \xi$ of radius $r^h(\xi_0, x) = a|\kappa(x)|/2$ will have $\mathcal{R}^i\xi_0$ in the domain of definition of $\mathcal{K}^{ah}$ for $i = 1, \cdots, N$ and $r^h_{\min}(\mathcal{R}^N\xi_0, \mathcal{R}^N x) \geq C \cdot a$.

The proof of Proposition C.4 will be the consequence of several lemmas.

Throughout the following lemmas we will suppose that $a > 0$ is sufficiently small so that a holomorphic disc $\xi$ centered at $x$ with $r^h(\xi, x) = a|\kappa(x)|$ is entirely within the domain of definition for $\mathcal{K}^{ah}$. This is possible by Proposition C.1.

Lemma C.5. If $\xi$ is any horizontal holomorphic curve centered at $x \in \mathcal{C} \setminus \{\alpha_{\pm}\}$ of radius $r^h(\xi, x) = a|\kappa(x)|$, then the restriction of $\mathcal{R}$ to the subdisc $\xi_0 \subset \xi$ of radius $r^h(\xi_0, x) = a|\kappa(x)|/2$ has bounded horizontal distortion.

Proof. Let $r = r^h(\xi_0, x)$. The function $\chi_{\xi_0} = \pi \circ \mathcal{R} \circ (\pi|\xi_0|)^{-1}$ extends to a univalent function in the disk $D(\phi, 2r)$, since $\xi_0$ is the restriction of $\xi$ to half of its radius. The conclusion then follows from the Koebe Distortion Theorem. □

In particular, we will have $r^h_{\min}(\mathcal{R}\xi_0, \mathcal{R}x) \asymp r^h_{\max}(\mathcal{R}\xi_0, \mathcal{R}x)$ and also there is a uniform constant $d \geq 1/4$ so that $r^h_{\min}(\mathcal{R}\xi_0, \mathcal{R}x) \geq d \cdot r^h_{\min}(\mathcal{R}\xi_0, \mathcal{R}x)$.

Recall the point $\alpha = (\pi, 1)$, which is mapped by $\mathcal{R}$ to the high temperature fixed point $\beta_1 = (0, 1)$.

Lemma C.6. Given $\kappa > 0$ there exists $C_0 > 0$ so that for any $a > 0$ we have the following property. If $\xi$ and $\xi_0 \subset \xi$ are as in Lemma C.5 and are based at a point
where $x \in C \setminus \{ \alpha_{\pm} \}$ in an appropriately small neighborhood of $\alpha_{\pm}$ with a bounded slope: $|\kappa(x)| \leq \kappa$, then

$$ r^h_{\min}(R\xi_0, Rx) \geq C_0 \cdot a \text{dist}^h(Rx, \alpha). $$

**Proof.** Let $x = (\epsilon, \tau)$.

Let us select $c = c(a)$ in such a way that any horizontal curve $\xi$ of size $\geq a\epsilon$ centered in one of the parabolic sectors $\{|\kappa - \epsilon| \leq c|\epsilon|\}$ near $\alpha_{\pm}$ crosses the corresponding curve $S_{\pm}$. The image $R\xi$ of such a curve crosses $I_{\pm}$, so that $r^h_{\max}(R\xi, Rx) \geq \text{dist}^h(Rx, \alpha)$. This is sufficient, since $r^h_{\min}(R\xi_0, Rx) \simeq r^h_{\max}(R\xi_0, Rx)$.

On the other hand, if $|\kappa - \epsilon| \geq |\epsilon|$ then $\text{dist}^h(Rx, \alpha) \simeq |\kappa - \epsilon|$ by Lemma B.1. Then, Lemmas B.2 and C.5 imply that

$$ r^h_{\min}(R\xi_0, Rx) \geq d\lambda^h(x) \kappa(x) \geq C_0 \cdot a |\kappa - \epsilon| \simeq \text{dist}^h(Rx, \alpha). $$

$$□$$

We now set up a complex neighborhood of $\beta_1$ designed so that suitable holomorphic curves $\eta$ near $\beta_1$ can regrow to definite size: Let

$$ V^c = \{ \phi, t \in C^c : |\tau| \leq \hat{\tau}, |\text{Im}\phi| < \hat{\epsilon} \}, $$

$$ U^c = \{ \phi, t \in V^c : |\epsilon(\phi)| < \epsilon \}. $$

They are complex versions of the regions $V$ and $U$ from §6.2. We will take $\hat{\tau}$ sufficiently small relative to $\hat{\epsilon} > 0$ so that $V^c \setminus U^c$ lies in the domain of definition of the complex extension of $K^{ab}$.

Choosing $\hat{\tau}$ sufficiently small compared to $\hat{\epsilon}$, we can ensure that $R$ is uniformly horizontally expanding on any horizontal holomorphic curve $\xi \subset V^c \setminus U^c$. (If follows by continuity from (B.10).)

**Lemma C.7.** Given $0 < r_{\min} < r_{\max}$ there exists $C_1 > 0$ so that for any $b > 0$ and any $x \in V \setminus U \subset C$ there is an iterate $n(x)$ with the following property. If $\eta \subset V^c \setminus U^c$ is a horizontal holomorphic curve centered at $x$ with

$$ r_{\min} \leq r^h_{\min}(\eta, x) < r^h_{\max}(\eta, x) < r_{\max} \quad \text{and} \quad r^h_{\min}(\eta, x) \geq b \text{dist}^h(x, \beta_1) $$

then $R^i\eta \subset V^c \setminus U^c$ for $0 \leq i \leq M$ and $r^h_{\min}(R^M\eta, R^Mx) \geq C_1 \cdot b$. Moreover, $C_1$ depends only on $r_{\max}/r_{\min}$.

**Proof.** The standard distortion estimates near the hyperbolic fixed point $\beta_1$ show that the discs $V^c \eta$ grow at the same rate as the horizontal distances between any point of $R^i\eta$ and $\beta_1$. $□$

**Proof of Proposition C.4:** Equation (B.6) gives that $DR$ expands horizontal vectors based at such points by $O(1/|\epsilon(\xi)|)$. So, we can assume that $a$ is sufficiently small so that $R\xi$ is in the domain of definition of $K^{ab}$. Moreover, using (B.3) we can choose $\kappa \leq \kappa$ so that if $\xi$ is centered at $x$ with $|\kappa(x)| \leq \kappa$ then $R^i\xi \subset V^c \setminus U^c$ for $i = 1, 2$.

Lemma C.5 gives that $R$ has bounded horizontal distortion on the subdisc $\xi_0 \subset \xi$ of radius $a|\epsilon(x)|/2$.

If $|\kappa(x)| \geq \kappa$ then Lemma B.2 implies that $\lambda^h_{\min}(x) \geq K/|\epsilon(x)|$. Together with bounded distortion, this is sufficient to give that $r^h_{\min}(R\xi_0, Rx) \geq C \cdot a$.

If $|\kappa(x)| \leq \kappa$ then Lemma C.6 gives that $r^h_{\min}(R\xi_0, Rx) \geq C_0 \cdot a \text{dist}^h(Rx, \alpha)$. There is some $C_0 > 0$ so that after one further iterate we have

$$ r^h_{\min}(R^2\xi_0, R^2x) \geq C_0 \cdot a \text{dist}^h(R^2x, \beta_1). $$
Since the horizontal distortion of $\mathcal{R}^2$ is also bounded on $\xi_0$, there is a uniform bound on $r^h_{\text{max}}(\mathcal{R}^2_\xi, \mathcal{R}^2_x)/r^h_{\text{min}}(\mathcal{R}^2_\xi, \mathcal{R}^2_x)$. Lemma C.7 then gives $M$ further iterates so that $\mathcal{R}^{M+2}\xi \subset \mathcal{V} \subset \mathcal{U}^c$ and

$$r^h_{\text{min}}(\mathcal{R}^{M+2}_\xi, \mathcal{R}^{M+2}_x) \geq C \cdot a.$$  

\[ \square \]

**Appendix D. Critical locus and Whitney folds**

D.1. **Critical locus.**

D.1.1. **Five lines and a conic.** The Jacobian of $\hat{R} : \mathbb{C}^3 \to \mathbb{C}^3$ (2.18) is equal to

$$\det D\hat{R} = 32V(UW - V^2)(U + W)(U^2 + V^2)(W^2 + V^2),$$

so its critical locus comprises 6 complex planes (where we count $\{U + W = 0\}$ only once, without multiplicity) and the cone $\{UW = V^2\}$. They descend to 6 complex lines and one conic on $\mathbb{CP}^2$:

- $L_0 := \{V = 0\}$ = line at infinity,
- $L_1 := \{UW = V^2\}$ = conic $\{uw = 1\}$,
- $L_2 := \{U = -W\} = \{u = -w\}$,
- $L_3^\pm := \{U = \pm iV\} = \{u = \pm i\}$,
- $L_4^\pm := \{W = \pm iV\} = \{w = \pm i\}$.

(Here the curves are written in the homogeneous coordinates $(U : V : W)$ and in the affine ones, $(u = U/V, w = W/V)$.) The configuration of these curves is shown in Figure 4.1.

The following general lemma shows that this coincides with the critical locus of $R$ on $\mathbb{CP}^2$:

**Lemma D.1.** Let $\hat{R} : \mathbb{C}^{m+1} \to \mathbb{C}^{m+1}$ be a homogeneous polynomial, and let $R : \mathbb{CP}^m \to \mathbb{CP}^m$ be the corresponding rational map of the projective space. Let $\hat{z} \in \mathbb{C}^{m+1}$ be such that $\hat{R}(\hat{z}) \neq 0$ (so that $z := \pi(\hat{z})$ is not a point of indeterminacy of $R$). Then $\hat{z}$ is a critical for $\hat{R}$ iff $z$ is critical for $R$.

**Proof.** Let $z$ be critical for $R$; then there exists a non-vanishing tangent vector $v \in T_z \mathbb{CP}^m$ such that $D\hat{R}(z) \cdot v = 0$. Let $\hat{v}$ be a lift of $v$ to $T_{\hat{z}} \mathbb{C}^3$. Then $D\hat{R}(\hat{z}) \cdot \hat{v} = \lambda \hat{R}(\hat{z})$ for some $\lambda \in \mathbb{C}$. On the other hand, $D\hat{R}(\hat{z}) \cdot \hat{z} = \mu \hat{R}(\hat{z})$ for some $\mu \in \mathbb{C}$. This shows that $D\hat{R}(\hat{z})$ is not injective.

Vice versa, by Euler’s formula, $D\hat{R}(\hat{z}) \cdot \hat{z} = d \hat{R}(\hat{z})$ where $d = \deg \hat{R}$. Hence, if $z$ is not a point of indeterminacy then $\hat{R}$ is non-degenerate along the complex line spanned by $\hat{z}$. So, if $D\hat{R}(\hat{z}) \cdot \hat{v} = 0$ then $\hat{v}$ is linearly independent of $\hat{z}$, and hence it projects to a non-vanishing vector $v \in \text{Ker} D\hat{R}(z)$.  

\[ \square \]

D.1.2. **Critical points on the exceptional divisor.** To complete the picture, we need to take an account of the critical points hidden inside the points of indeterminacy, $a_\pm$. To make them visible, we blow up $\mathbb{CP}^2$ at $a_\pm$ and lift $R$ to a holomorphic map $\hat{R} = Q \circ \hat{g} : \mathbb{CP}^2 \to \mathbb{CP}^2$.

By symmetry, it is enough to analyze the blow-up of $a_+$. Jacobian of $\hat{g}$ (B.1) on the exceptional divisor $\{\xi = 0\}$ is equal to $2i(\chi - 1)/(\chi + 1)^2$, so $\hat{g}$ has two critical
points on it, \( \chi = -1 \) and \( \chi = 1 \), which are the intersections of the exceptional divisor with the collapsing line \( \tilde{L}_2 \) and the separatrix \( \tilde{L}_1 \) respectively (recall that \( \tilde{L} \) stands for the lift of \( L \) to \( \tilde{CP}^2 \)). The first critical point is mapped by \( \tilde{R} \) to the low temperature fixed point \( b_0 \), while the second one is mapped to \((-1, -1)\), which is a preimage of the high temperature fixed point \( b_1 \).

Also, points \( \chi = \infty \) and \( \chi = 0 \) are mapped by \( \tilde{g} \) to the coordinate lines \( \{u = 0\} \) and \( \{w = 0\} \) respectively which are critical for the squaring map \( Q \). It creates two more critical points on the exceptional divisor, its intersections with the critical lines \( \tilde{L}_3^+ \) and \( \tilde{L}_4^- \).

D.2. Complex Whitney folds. To simplify calculations near the critical points, it is convenient to bring \( \tilde{R} \) to a normal form. A complex Whitney fold is a generic and the simplest one. Let \( \tilde{R} : (\mathbb{C}^2, 0) \rightarrow (\mathbb{C}^2, 0) \) be a germ of holomorphic map with a critical point at 0. The map \( \tilde{R} \) (and the corresponding critical set) is called a complex Whitney fold if

(W1) The critical set \( L \) is a non-singular curve near 0;
(W2) \( DR(0) \) has rank 1 and \( \text{Ker} DR(0) \) is transverse to \( L \);
(W3) The second differential \( D^2 R(0) \) is not vanishing in the direction of \( \text{Ker} DR(0) \).

Lemma D.2. A Whitney fold can be locally brought to a normal form \((u, w) \mapsto (u, w^2)\) in holomorphic coordinates.

Proof. Since \( L \) is non-singular and \( \text{Ker} DR(0) \) is transverse to \( L \), the image \( L' = R(L) \) is a non-singular holomorphic curve near 0, so we can select local coordinates in such a way that both \( L \) and \( L' \) locally coincide with the axis \( \{w = 0\} \). Then \( u' = \phi(u, w) \) with \( \partial_u \phi(0) \neq 0 \), so \((u', w)\) can be selected as local coordinates in the domain of \( R \). This brings \( R \) to a fibered map \( u' = u, \ w' = \psi(u, w) \).

Since \( \{w = 0\} \) is in the critical locus of \( R \),

\[ \psi(w) = p_2(u)w^2 + p_3(u)w^3 + \ldots \]

Moreover, by definition of the fold, \( \psi_2(0) \neq 0 \), so we can select a local branch of the square root \( w\sqrt{p_2(u) + p_3(u)w + \ldots} \) as a local coordinate replacing \( w \). This brings \( R \) to the desired form. \( \Box \)

Lemma D.3. All critical points of \( \tilde{R} \) except the fixed points \( e, e' \), the collapsing line \( \tilde{L}_2 \), and two points \( \{\pm(i, i)\} = \tilde{L}_3 \cap \tilde{L}_4 \), are Whitney folds.

Proof. Let us treat the components of the critical locus one by one.

Separatrix \( L_0 \). In affine coordinates \( \xi = U/W, \ \eta = V/W \), the map \( R \) near \( L_0 = \{\eta = 0\} \) looks like this:

\[ \xi' = \left( \frac{\xi^2 + \eta^2}{1 + \eta^2} \right)^2 = \xi^4 (1 + O(\eta^2)), \]

\[ \eta' = \eta^2 \left( \frac{1 + \xi}{1 + \eta} \right)^2 = \eta^2 (1 + \xi)^2 (1 + O(\eta^2)), \]

which shows that \( L_0 \) is a fold outside the fixed point \( b_0 (\xi = 0) \) and the collapsing line \( L_2 (\xi = -1) \). (The other fixed point \( b_1 \) lies at infinity, \( \xi = \infty \)).
Separatrix $\tilde{L}_1$. In local coordinates $(u, \tau = uw - 1)$, the map $R$ near $L_1 = \{\tau = 0\}$ looks like this:

$$u' = \left(\frac{u^2 + 1}{u + (\tau + 1)/u}\right)^2 = u^2 \left(1 + O\left(\frac{\tau}{u^2 + 1}\right)\right),$$

$$\tau' = \frac{\tau^2}{(u + w)^2} \left(-2 + \frac{\tau^2}{(u + w)^2}\right),$$

(D.1)

which shows that $L_1$ is a fold outside the indeterminacy points $\{u = \pm i\} = L_1 \cap \{u + w = 0\}$ (and outside the fixed points $b_0$ and $b_1$ at infinity).

Let us now analyze the intersection $\tilde{a}_+ = (u = i, \chi = 1)$ of $\tilde{L}_1$ with the exceptional divisor $L^+_\text{exc}$ (the intersection with $L^-\text{exc}$ is symmetric). Let us use local coordinates $(\xi = u - i, \lambda = \chi - 1)$ near $\tilde{a}^+$. Representation (B.1) of $\tilde{g}$ near $L^+_\text{exc}$ gives:

$$u = i + \frac{1}{2}(\xi - i\lambda) + \frac{i}{4}\lambda^2 - \frac{1}{4}\xi\lambda + \ldots,$$

$$w = -i + \frac{1}{2}(\xi - i\lambda) + \frac{i}{4}\lambda^2 + \frac{3}{4}\xi\lambda + \ldots,$$

so the vanishing direction for $D\tilde{g}(\tilde{a}_+)$ is $d\xi = id\lambda$. On the other hand, in these coordinates the separatrix $\{uw = 1\}$ assumes the form $\xi + i\lambda + \xi^2\lambda = 0$, so it is a non-singular curve tangent to $\{d\xi = -i d\lambda\}$ at $\tilde{a}_+$. This yields conditions (W1) and (W2). Moreover, at the kernel direction $d\xi = i d\lambda$, the second differential assumes the form $(0, id\lambda^2)$, so it is non-vanishing.

Thus, $\tilde{a}_+$ is a Whitney fold for $\tilde{g}$. Since the squaring map $Q$ is non-singular at $(i, -i)$, it is a a Whitney fold for $R = \tilde{g} \circ Q$ as well.

Lines $\tilde{L}_{3}^\pm$ and $\tilde{L}_{4}^\pm$. These lines intersect the line at infinity at the fixed points $b_0$ and $b_1$, so we need to analyze only their affine parts. The map $\tilde{g}$ is non-singular on these lines (including their intersections with the exceptional divisors), and it maps them isomorphically onto the coordinate axes $\{u = 0\}$ and $\{w = 0\}$. Outside the origin 0, these axes are Whitney folds for the squaring map $Q$. Hence the lines $L^\pm_3$ and $L^\pm_4$ are folds for $R$ outside points $\{\pm(i, i)\} = \tilde{g}^{-1}(0) = \tilde{L}_3 \cap \tilde{L}_4$.

D.2.1. Double points. A double point of a holomorphic curve $X$ is a point $a \in X$ such that the germ of $\gamma$ at $a$ consists of two regular branches, $X_1$ and $X_2$, meeting at $a$. A double point is called transverse if the branches $X_i$ intersect transversely at $a$. Otherwise, it is called tangential.

We say that a regular curve $L$ intersects a curve $X$ transversely at the double point $a \in X$ if it intersects transversely both branches $X_i$. Such intersection has multiplicity 2.

Lemma D.4. Let $R$ be a Whitney fold at $a$, and let $X$ be a germ of regular holomorphic curve with the first order tangency to the critical value locus $R(L)$. Then the pullback $R^*X$ has a transverse double point at a intersecting $L$ transversally.

Proof. In the normal coordinates, the pullback under $R$ of a regular curve $w = cu^2(1 + O(u))$, $c \neq 0$, tangent to $R(L) = \{w = 0\}$ is a pair of regular curves $w = \pm \sqrt{cu}(1 + O(u))$. \qed
Lemma D.5. Let \( \pi : (\tilde{M}, \mathcal{E}_{\text{exc}}) \to (M, a) \) be the blow-up of \( M \) at \( a \), and let \( \tilde{p} \in \mathcal{E}_{\text{exc}} \). Let \( \tilde{X} \subset \tilde{M} \) be a holomorphic curve with a transverse double point at \( \tilde{p} \) that intersects \( \mathcal{E}_{\text{exc}} \) transversely. Then \( X = \pi(\tilde{X}) \) is a holomorphic curve in \( M \) with a (first order) tangential double point at \( a \).

Proof. Let us use the local coordinates \((u, v, m = v/u)\) from the definition of the blow-up. In this coordinates, the pencil of lines \( m - m_0 = \lambda u, \lambda \in \mathbb{C} \) centered at \((0, 0, m_0) \in \mathcal{E}_{\text{exc}} \) projects to the pencil of parabolas \( v = (\lambda^{-1}u + m_0)u \) in \( M \) tangent to the line \( v = m_0u \).

Appendix E. Computational proof of horizontal expansion

We will give an alternative, computational, proof that \( \mathcal{R} : C \to C \) is horizontally expanding, which, unlike Theorem 8.1, does not result in a lower bound on the rate of expansion.

Proposition E.1. The map \( \mathcal{R} : C \to C \) is horizontally expanding on \( C \) with respect to the horizontal cone field \( K^h \).

Lemma E.2. Let \( x \in C_1 \) then

\[
\text{(E.1)} \quad d(\phi \circ \mathcal{R})(v) > d\phi(v) \quad \text{for any } v \in K^h(x).
\]

Proof. Recall the region \( V' \) used in §6.2 when constructing \( K^h \). If \( x \in C_1 \setminus V' \), then \( K^h(x) = K^{ah}(x) \). Linearity of (E.1) allows us to assume that \( d\phi(v) = 1 \) in order to check that \( d(\phi \circ \mathcal{R})(v) \geq 1 \). Furthermore, the minimum of \( d(\phi \circ \mathcal{R})(v) \geq 1 \) over all such \( v \in K^{ah}(x) \) occurs at one of the vectors \( v_{\pm} = (1, \pm \sqrt{1 - t^2}) \) on the boundary of \( K^{ah}(x) \).

Using (B.6) we find

\[
\text{(E.2)} \quad d(\phi \circ \mathcal{R})(v_{\pm}) = 4 \frac{1 + t^2 \cos(2 \phi) \mp \sin(2 \phi) t \sqrt{1 - t^2}}{1 + 2 t^2 \cos(2 \phi) + t^4}
\]

For \( x \in C \setminus \{ \alpha_{\pm} \} \) let \( \lambda(x) \) be given by the minimum of the two terms in (E.2). It is a continuous function.

Equivalent to \( \lambda(x) > 1 \) is

\[
\text{(E.3)} \quad 3 - t^4 + 2 t^2 \cos 2 \phi \mp 4 \sin 2 \phi t \sqrt{1 - t^2} > 0,
\]

which holds when \( t = 0 \) or when \( t = 1 \) and \( \phi \neq \pm \pi/2 \).

If we let \( s = |\sin 2\phi| \) so that \( |\cos 2\phi| = \sqrt{1 - s^2} \), then (E.3) is bounded below by

\[
g(s, t) := 3 - t^4 - 2 t^2 \sqrt{1 - s^2} - 4 s t \sqrt{1 - t^2},
\]

which we check is positive for \((s, t) \in [0, 1] \times (0, 1)\). Because \( g(s, t) \) is continuous on \([0, 1]^2\) with \( g(1/2, 1/2) = 1.63 > 0 \), it suffices to check that \( g(s, t) \neq 0 \) for \((s, t) \in [0, 1] \times (0, 1)\).

Replace \( g(s, t) = 0 \) with \( 3 - t^4 - 4 s t \sqrt{1 - t^2} = 2 t^2 \sqrt{1 - s^2} \). After squaring both sides, we find

\[
(9 - 10 t^4 + t^8) - \left(8 t (3 - t^4) \sqrt{1 - t^2}\right) s + \left(16 t^2 - 12 t^4\right) s^2
\]

Considered as a quadratic polynomial in \( s \) the discriminant is:

\[
-16 t^4 (1 - t^2) (t^4 + 2 t^2 + 9).
\]

For each \( t \in (0, 1) \) this is negative, so that there are no real roots for \( s \).
Now consider $x \in \mathcal{V}$. If $x \in \mathcal{V} \setminus \mathcal{U}'$, (E.1) follows from (6.6).

If $x \in U'$ the minimum of $d(\phi \circ R)(v)$ occurs at $v_{\pm} = (1, \pm w(x))$, where $w(x) \sim |\epsilon(x)|/3$. Equation (B.8) gives

$$d(\phi \circ R)(v_{\pm}) = \frac{2}{\epsilon^2 + \tau^2} \left( \epsilon^2 + \tau^2 \frac{\epsilon^2}{3} \right) \geq \frac{4 \epsilon^2/3 + 2 \tau}{\epsilon^2 + \tau^2} > \frac{4}{3}.$$  

Thus, $\lambda(x) > 1$ for all $x \in C \setminus \{\alpha_{\pm}\}$. □

**Remark E.1.** Lemma E.2 give non-uniform expansion for horizontal tangent vectors $v \in K_h(x)$ under the first iterate of $R$. It is not possible for this expansion to be uniform because (E.2) limits to 1 as a point $x$ approaches the indeterminate points $\alpha_{\pm}$ along the parabolas given by $\tau = \epsilon^2/2$.

**Proof of Proposition E.1:** Recall the neighborhood $U$ of $\alpha_{\pm}$ that was constructed in §6.2. The estimates from the proof of Lemma E.2 give uniform expansion at points $x \in C_1 \setminus U$. According to Lemma 6.5, we have $R(U) \cap U = \emptyset$, so that vectors $x \in K_h(x)$ experience a definite amount of expansion under at least every other iterate. □

**Appendix F. Extra bits of stat mechanics**

**F.1. The Lee-Yang Theorem.** To prove the Lee-Yang Theorem, we need to consider a more general, anisotropic, Ising model. It is parameterized by a symmetric matrix $J = (J_{vw})_{v,w \in E}$ of couplings between the atoms and by a vector $h = (h_v)_{v \in V}$ of interaction strengths of the external field with the atoms. Then the energy of a spin configuration $\sigma : V \to \{\pm 1\}$ assumes the form

$$-H(\sigma) = < J \sigma, \sigma > + < h, \sigma >.$$ (F.1)

It is convenient to assume that $\Gamma$ is a complete graph without loops (connecting a vertex to itself), but to to allow some of the coupling constants vanish. In the ferromagnetic model, $J_{vw} \geq 0$.

Let us consider the “support” of a configuration $\sigma$,

$$\mathcal{V}(\sigma) = \{c \in \mathcal{V} : \sigma(v) = -1\},$$

and let

$$\mathcal{E}(\sigma) = \{(v, w) : v \in \mathcal{V}(\sigma), \ w \in \mathcal{V} \setminus \mathcal{V}(\sigma)\}.$$ Let $l(J)$ and $l(h)$ be the the sums of all components of $J$ and $h$ respectively. We will work with a modified Hamiltonian

$$-\tilde{H}(\sigma) = -H(\sigma) - l(J) - l(h) = -2 \sum_{(vw) \in \mathcal{E}(\sigma)} J_{vw} - 2 \sum_{v \in \mathcal{V}(\sigma)} h_v.$$  

Let us introduce the temperature-like and field-like variables:

$$t_{vw} = e^{-2J_{vw}/T} \quad \text{and} \quad \zeta_v = e^{-2h_v/T}.$$ Given subsets $X \subset \mathcal{V}$ and $Y \subset \mathcal{E}$, we will use notation

$$\zeta^X = \prod_{v \in X} \zeta_v, \quad t^Y = \prod_{(vw) \in Y} t_{vw}$$

In this notation, we obtain the following expression for the modified Gibbs weights:

$$\tilde{W}(\sigma) = \exp(-\tilde{H}(\sigma)/T) = W(\sigma) t^\mathcal{E} \zeta^{\mathcal{V}(\sigma)} = t^{\mathcal{E}(\sigma)} \zeta^{\mathcal{V}(\sigma)}$$
and for the modified partition function:

\[(F.2) \tilde{Z} = t^E \zeta^V Z = \sum_{\sigma} t^{E(\sigma)} \zeta^{V(\sigma)}.\]

Obviously, the modification does not affect the roots of the partition function (modulo clearing up the denominator), so we can work with \(\tilde{Z}\) instead of \(Z\).

**Lemma F.1.** Fix arbitrary \(t_{vw} \in [-1, 1]\). If \(\tilde{Z}(\zeta_1, \ldots, \zeta_n) = 0\) and \(|\zeta_i| \leq 1\) for \(i = 1, \ldots, n-1\), then \(|\zeta_n| \geq 1\), where the inequality is strict unless all \(|\zeta_i| = 1\), \(i = 1, \ldots, n-1\).

**Proof.** To simplify notation and to emphasize dependence on \(n = |V|\), we let \(P_n \equiv \tilde{Z}\). We will carry induction in \(n\). Without loss of generality we can assume that \(t_{vw} \neq 0, \pm 1\).

For \(n = 2\), we have

\[P_2(z_1, z_2) = 1 + t_{12}z_1 + t_{21}z_2 + \zeta_1z_2,\]

which implies

\[\zeta_2 = -\frac{1 + t_{12}z_1}{t_{21} + \zeta_1}.\]

Since \(t_{12} = t_{21} \in (-1, 1)\), this is a Möbius map sending \(D\) to \(\mathbb{C} \setminus \overline{D}\).

To pass from \(n\) to \(n+1\), observe that

\[P_{n+1}(\zeta_1, \ldots, \zeta_{n+1}) = P_n(u_1, \ldots, u_n) + \zeta_1 \ldots \zeta_n P_n(v_1, \ldots, v_n),\]

where \(u_i = t_{i,n+1}\zeta_i\), \(v_i = t_{i,n+1}/\zeta_i\).

**Remark F.1.** This formula is directly related to the Basic Symmetry of the Ising model which is ultimately responsible for the Lee-Yang Theorem.

If \(P_n = 0\) then

\[(F.3) \zeta_{n+1} = -\frac{1}{\zeta_1 \ldots \zeta_n} \frac{P_n(u_1, \ldots, u_n)}{P_n(v_1, \ldots, v_n)}.\]

If \(\zeta_i \in \hat{C} \setminus \overline{D}\) for \(i = 1, \ldots, n\), then \(|v_i| < 1\) and by the Induction Assumption, \(P_n(v_1, \ldots, v_n) \neq 0\). Hence the right-hand side of (F.3) is a well-defined holomorphic function in the polydisk \(\Delta^n := (\hat{C} \setminus \overline{D})^n\). On its Shilov boundary

\[\partial^s \Delta^n = T^n \equiv \{ |\zeta_i| = 1, \quad i = 1 \ldots, n\}\]

we have \(v_i = \bar{w}_i\). Since \(P_n\) has real coefficients, we conclude that \(|\zeta_{n+1}| = 1\) on \(T^n\). By the Maximum Principle, \(|\zeta_{n+1}| \leq 1\) in \(\Delta^n\), with equality only on \(T^n\), and we are done. \(\square\)

**General Lee-Yang Theorem ([YL, LY]).** Fix \(J_{vw} \in [0, +\infty]\), and assume \(h_v/h_w \in \mathbb{R} \cup \{\infty\}\). Then, all zeros of the partition function \(Z(\zeta_1, \ldots, \zeta_n)\) lie on the unit torus \(T^n\).

**Proof.** Under these circumstances, all \(\zeta_v = e^{-h_v/T}\) have the same modulus, which must be equal to 1 by the previous lemma. (The lemma is applicable since \(t_{vw} = e^{-2J_{vw}/T} \in [0, 1]\).) \(\square\)
To obtain the classical Lee-Yang Theorem, corresponding to Hamiltonian with magnetic moment $M$ given by (1.1), one sets $h_v \equiv h$. To get the result for Hamiltonian with magnetic moment $M$ given by (2.1), obtained by summing over magnetic moments of edges, one sets $h_v = h \cdot |v|/2$, where $|v|$ is the valence of the vertex $v$.

Many extensions and new proofs of this theorem have appeared since the 1950s: see Asano [A], Suzuki and Fisher [SF], Heilmann and Lieb [HL], Ruelle [R2, R4], Newman [N], Lieb and Sokal [LS], Borcea and Bråndén [BB] and further references therein. The proof given above is based upon the original idea of Lee and Yang [LY], compare [R3, Thm 5.1.2].

**F.2. The Lee-Yang Theorem with Boundary conditions.** Given any coupling $J_{vw} \in [0, +\infty]$, let $\Gamma' \subset \Gamma$ be the subgraph containing only the edges with $J_{vw} > 0$. The Lee-Yang Theorem with Boundary Conditions, stated in §2.1, is a consequence of the following more general statement:

**General Lee-Yang Theorem with Boundary Conditions.** Fix $J_{vw} \in [0, +\infty]$ and assume that $\Gamma' \subset \Gamma$ is connected and $h_v/h_w \in \mathbb{R} \cup \{\infty\}$. Let $\sigma_U \equiv +1$ for $U \subset V$ is given by $\{m + 1, \ldots, n\}$ with $1 < m < n$.

Then all of the zeros of the conditional partition function $Z^+(\zeta_1, \ldots, \zeta_m)$ lie in the open polydisc $\Delta^m = (\hat{C} \setminus \overline{D})^m$.

**Proof.** Since $\Gamma'$ is connected we can assume that $J_{1,n} > 0$ giving $|t_{1n}| < 1$. Let $\eta_i = \zeta_i \prod_{j=m+1}^n t_{ij}$ for $i = 1, \ldots, m$ so that $|\eta_i| \leq |\zeta_i|$ and $|\eta_1| < |\zeta_1|$.

The (modified) conditional partition function

$$\hat{Z}_{\Gamma'|\sigma_U}(\zeta_1, \ldots, \zeta_n) = t^{E_{\Gamma \setminus U}} Z_{\Gamma'|\sigma_U}(\zeta_1, \ldots, \zeta_n)$$

satisfies

$$\hat{Z}_{\Gamma'|\sigma_U}(\zeta_1, \ldots, \zeta_m) = \hat{Z}(\eta_1, \ldots, \eta_m),$$

where $\hat{Z}$ is the modified partition function corresponding to $\Gamma \setminus U$.

Since $h_v/h_w \in \mathbb{R} \cup \{\infty\}$, all of the $\zeta_i$ have the same modulus. If this common modulus is less than or equal to 1, then $|\eta_i| \leq 1$ and $|\eta_1| < 1$. Lemma F.1 gives

$$\hat{Z}_{\Gamma'|\sigma_U}(\zeta_1, \ldots, \zeta_m) = \hat{Z}(\eta_1, \ldots, \eta_m) \neq 0.$$ 

**Remark F.2.** The same statement holds if we assign $\sigma_U \equiv 0 > 0$ and the classical Lee-Yang Theorem can be obtained from it by taking a limit $\sigma_0 \to 0$.

**F.3. The Lee-Yang zeros in the 1D Ising model.** By means of the well-known “Transfer Matrix technique” (see [Ba]), one can find explicitly the Lee-Yang zeros of the 1D Ising model. Let $\Gamma_n$ be the linear chain with $n + 1$ vertices $\{0, 1, \ldots, n\}$. For simplicity, we will consider periodic boundary conditions: $\sigma(n) = \sigma(0)$ (so that our graph is the circle $\mathbb{Z}/n\mathbb{Z}$). This assumption does not affect the thermodynamical limit.

The Hamiltonian of this lattice is:

$$H_n(\sigma) = -\sum_{i=0}^{n-1} \{J\sigma(i)\sigma(i+1) + \frac{h}{2}(\sigma(i) + \sigma(i+1))\}.$$
Two neighboring spins \( \{ \sigma(i), \sigma(i + 1) \} \) contribute the following factor to the Gibbs weight (compare (2.16)):

\[
W(++) = e^{(J+h)/T} = \frac{1}{t z}, \quad W(+-) = W(-+) = e^{-J/T} = t, \quad W(--) = e^{(J-h)/T} = \frac{2}{t},
\]

which can be organized into the Transfer Matrix

\[
W = \begin{pmatrix} (t z)^{-1} & t \\ t & t^{-1} z \end{pmatrix}.
\]

We see that the partition function \( Z_n = \sum_\sigma \exp(-H_n(\sigma)/T) \) can be expressed as

\[
Z_n = \sum_\sigma W(\sigma_1, \sigma_2) \cdot W(\sigma_2, \sigma_3) \cdots W(\sigma_n, \sigma_1) = \text{tr} W^n = \tau_1^n + \tau_2^n,
\]

where \( \tau_{1,2} \) are the eigenvalues of \( W \).

Thus, the zeros of the partition functions are solutions of the equation

\[
\tau_1^n + \tau_2^n = 0,
\]

or

\[[F.4] \quad \frac{\tau_2}{\tau_1} = e^{i\alpha_k}, \quad \alpha_k = \frac{\pi}{n} + \frac{2\pi k}{n}; \quad k = 0, 1, \ldots, n - 1.\]

The eigenvalues \( \tau_{1,2} \) are the roots of the quadratic equation

\[
\tau^2 - pt + q = 0, \quad \text{where } p = \frac{1}{t} (z + \frac{1}{z}) = \frac{2}{t} \cos \phi, \quad q = \frac{1}{t^2} - t^2.
\]

This gives

\[
2 \cos \alpha_k = \frac{\tau_2}{\tau_1} + \frac{\tau_1}{\tau_2} = \frac{p^2}{q} - 2 = \frac{4 \cos^2 \phi_k}{1 - t^4} - 2,
\]

so

\[[F.5] \quad (1 - t^4) \cos^2 \frac{\alpha_k}{2} = \cos^2 \phi_k, \quad \text{where } z_k = e^{i\phi_k}.\]

Together with (F.4), this gives expression (1.3) for the zeros of the partition function.

Since the angles \( \alpha_k \) are equidistributed with respect to the Lebesgue measure \( d\alpha/2\pi \) on the circle, the distribution \( \rho_b d\phi \) of the Lee-Yang zeros is obtained by pushing this measure to the interval \([-1, 1]\) by \( \cos \), scaling it by \( \sqrt{(1 - t^4)} \) and then pulling it back to the circle by \( \cos \). The calculation gives expression (1.4):

\[
\rho_t(\phi) = \frac{1}{2\pi} \left| \frac{d\alpha}{d\phi} \right| = \frac{1}{2\pi} \left| \frac{d}{d\phi} \arccos \left( \frac{\cos \phi}{\sqrt{1 - t^4}} \right) \right| = \frac{|\sin \phi|}{2\pi \sqrt{1 - t^4 - \cos^2 \phi}}.
\]

---

\[\text{Different boundary conditions would result in } Z_n = a\tau_1^n + b\tau_2^n \text{ for appropriate } a \text{ and } b.\]

\[\text{which gives the \textquotedblleft Chebyshev measure\textquotedblright } dx/\sqrt{1 - x^2} \text{ on } [-1, 1]\]
F.4. **Diamond model as anisotropic regular 2D lattice model.** The diamond model can be viewed as the Ising model on the regular 2D lattice with a special anisotropic choice of the interaction parameters. Namely, let us consider a $2^n \times (2^n + 1)$ rectangle
\[ \Delta_n = \{(i, j) \in \mathbb{Z}^2 : 0 \leq i \leq 2^n - 1, 0 \leq j \leq 2^n\} \]
in $\mathbb{Z}^2$, with the Hamiltonian
\[ H_n(\sigma) = -\sum_{|x-y|=1} J(x, y)\sigma(x)\sigma(y) - \sum_{x \in \Delta_n} h(x)\sigma(x), \]
where
\[ h(i, j) = \begin{cases} h & \text{if } 0 < j < 2^n, \\ \frac{h}{2} & \text{if } j = 0, 2^n. \end{cases} \]
The interaction parameters $J(x, y)$ are defined as follows.

Representing any $j = 0, 1, \ldots, 2^n$ in the dyadic arithmetics,
\[ j = \sum_{k=0}^{n} j_k 2^k, \quad j_k \in \{0, 1\}, \]
let
\[ o(j) = \min\{k : j_k \neq 0\} \quad \text{if } j > 0; \quad o(0) = n. \]

Let us partition each horizontal level $\Delta_n(j) = \{(i, j) \in \Delta_n\}$ into $2^{n-o(j)}$ intervals $[s2^{o(j)}, (s+1)2^{o(j)}]$ of length $2^{o(j)}$, $s = 0, 1, \ldots, 2^{n-o(j)} - 1$. Let $\sim$ denote the corresponding equivalence relation.

Now we let
\[ J(x, y) = \begin{cases} J & \text{if } y - x = \pm(0, 1); \\ \infty & \text{if } y - x = \pm(1, 0) \quad \text{and} \quad x \sim y. \\ 0 & \text{otherwise.} \end{cases} \]

In other words, within a horizontal level $\Delta_n(j)$, non-equivalent sites do not interact, while the equivalent neighbors interact with infinite strength. Infinite interaction $J(x, y)$ is interpreted as condition $\sigma(x) = \sigma(y)$, so that the equivalent sites $x$ and $y$ can be identified. This leads to the diamond graph $\Gamma_n$. (Figure F.1 illustrates the
$4 \times 5$ rectangle, with the vertical solid lines representing interaction $J$ and horizontal dash lines representing the infinite interaction.) Moreover, the Hamiltonian (F.6) takes the form of (1.2):

$$H_n(\sigma) = -\frac{J}{2} \sum_{(x,y) \in E^n_v} \sigma(x)\sigma(y) - \frac{h}{2} \sum_{(x,y) \in E^n} (\sigma(x) + \sigma(y)),$$

where $E^n_v$ is the set of vertical edges.

Thus, we have obtained the diamond model.

F.5. Gibbs states. The thermodynamic limit of the Gibbs distributions for $DHL$ was studied by Griffiths and Kaufman [GK] and by Bleher and Zalyss [BZ2]. As noticed in [GK], there are uncountably many non-isomorphic injective limits of the hierarchical lattice $\Gamma_n$ as $n \to \infty$, which give rise to uncountably many non-isomorphic infinite hierarchical lattices. In [BZ2], limit Gibbs states on the infinite hierarchical lattices are constructed. It is proven that for any non-degenerate infinite hierarchical lattice, if $T < T_c$ and $h = 0$ then there exist exactly two pure infinite Gibbs states, in the sense of Dobrushin-Lanford-Ruelle, while if $T \geq T_c$ or $h \neq 0$ then the infinite Gibbs state is unique.

Appendix G. Open Problems

Problem G.1 (Critical exponents for the low-temperature intervals). A consequence of Theorem 11.1 and Corollary 11.2 is that unstable Lyapunov exponents $\chi^u$ exist at almost every point of $C_1$. However, the union of all endpoints of the intervals from $O_t = W^s(B) \cap T_t$, taken over all $t \in [t_c, 1)$, has measure zero. Thus, we do not know that “most endpoints” have Lyapunov exponents. Do Lyapunov exponents and hence, by Proposition 13.4, weak critical exponents exist at the endpoints of the intervals from $O_t$?

Problem G.2 (Principal stable tongues). Consider the principal stable tongues $\Upsilon_\pm$. Are $\Upsilon_\pm$ bounded by high-temperature hairs of some positive length?

If this is the case, the discussion from Problem G.1 gives that for high enough values of $t$, the critical exponents $\sigma^h = 1$ at the endpoints of the intervals formed by $\Upsilon_\pm \cap T_t$.

The question can be asked for any of the stable tongues.

Problem G.3 (Endpoints of hairs). Recall the set $\mathcal{E}$ of endpoints to the high-temperature hairs that constructed in §12.6. According to Corollary 12.14, $\mathcal{E}$ has Lebesgue measure zero.

(a) What is the Hausdorff dimension of $\mathcal{E}$?

(b) Do any of the high-temperature hairs contain their endpoints, i.e. is there any endpoint within $W^s(T)$?

(c) Is $W^s(T)$ “straight hairy brush” in the sense of [AO]? One consequence would be that the endpoints of the high-temperature hairs must accumulate from both sides to every point on every high-temperature hair. In particular, this would give a negative solution to Problems G.2 and G.1(b).

These questions are partly motivated by the structure of the Devaney hairs for the exponential maps, see [DT, McM, Kar].
Problem G.4 (Control of expansion). Do we have
\[
\limsup \frac{\log d(\phi \circ R^n)}{n} \leq 4
\]
for any \( v \in K(x) \) based at any \( x \in C_1 \)? This bound would give continuity in \( \phi \) of the density \( \rho_t(\phi) \) by an estimate similar to the proof of Propositions 13.2 and 13.4. Notice, however, that it does not hold for the first iterate: One can see from (B.8) that if \( x \) approaches \( \alpha \pm \tau/\epsilon = \bar{\kappa} \), then the horizontal expansion of vectors in \( K^h(x) \) blows up like \( 1/\tau \).

Problem G.5 (Critical temperatures and regularity). Given \( \gamma \in F^c \), there are \( 0 < t^{-c}_c(\gamma) \leq t^+_c(\gamma) \leq 1 \) so that points on \( \gamma \) below \( t = t^+_c(\gamma) \) are in \( W^s(B) \) and points above \( t = t^+_c(\gamma) \) are in \( W^s(T) \). We call the points on \( \gamma \) having \( t^+_c(\gamma) \leq t \leq t^+_c(\gamma) \) the \( \gamma \)-critical temperatures.

(a) Is there a unique \( \gamma \)-critical temperature \( t_c(\gamma) := t^+_c(\gamma) = t^-_c(\gamma) \) on each \( \gamma \in F^c \)?
(b) The union of \( \gamma \)-critical temperatures over all \( \gamma \in F^c \) is invariant under \( R \). Is there a “natural” invariant measure \( \nu_{\text{crit}} \) supported on this set? What is the entropy of this measure?
(c) It is a consequence of Propositions 9.2 and 10.1 that each leaf \( \gamma \in F^c \) is real analytic below \( t^+_c(\gamma) \) and \( C^1 \) above \( t^+_c(\gamma) \). Does \( \gamma \) have only finite smoothness within the range of \( \gamma \)-critical temperatures?
(d) Proposition 14.1 gives a partial answer to the previous question for periodic leaves. A natural open question here is whether a periodic leaf can contain a neutral periodic point?

Cylinder maps having property (a) on almost every leaf are constructed in [BM, §3]. To ask questions (a) and (c) for almost every leaf in our situation, one must first choose a transverse invariant measure on \( F^c \). With respect to \( \mu_t \), almost every leaf is in the union of stable tongues and the result is trivial. The question is more interesting with respect to the transverse measure induced on \( F^c \) by Lebesgue measure on \( T \).

Appendix H. Table of notation

In the course of this paper various objects appear in parallel in two coordinate systems: the “physical coordinates” \((z,t)\) and the affine coordinates \((u,v) \mapsto [u : 1 : v] \).\(^{34}\) They are related by the semi-conjugacy \( \Psi \) from §3. We have attempted (not fully consistently) to use similar notation for corresponding objects, roughly using calligraphic and Greek symbols in the physical coordinates and the corresponding non-calligraphic and Latin symbols in the affine coordinates. For reader’s convenience, some of the notation is collected in the following table:

\(^{34}\)If not to count homogeneous coordinates \((U : V : W)\) and angular coordinates \((\phi,t)\) as systems in their own right.
