

Math53: Ordinary Differential Equations Autumn 2004

Midterm I Information

Tuesday, 10/19, 2:15-3:05p.m.

General Information

This will be a closed-book, closed-notes exam. No calculators will be allowed. Midterm I will cover Chapters 1-4 of the textbook, but the focus will be on Sections 1.2, 1.3, 2.1, 2.2, 2.4, 2.6, 2.7, 2.9, 4.1, 4.3, 4.5, and 4.6. I suggest you look in detail over these sections, the two lecture summaries handed out in class, and the solutions to the first three problem sets. There will be no application-style problems, like 2.3:4, 2.5:4, or 3.1:12 on the midterm, but they could appear on the final exam.

The material covered in the first third of the course is fundamental to the rest of the course. Please make sure you can do all problem set exercises from the above twelve sections and perhaps some other related problems from the textbook and can finish the practice tests in fifty minutes. You are very much encouraged to come to office and tutoring hours.

Pre-Midterm I Office and Tutoring Hours

Over the next few days, I will have office hours on Sunday 5-7 in 383N and Tuesday 9-12 in 383UU. Ken will hold office hours on Tuesday, 12³⁰-2 in 380U1, but *not* on Monday morning. Ziyu's office hours will be on Monday morning, 8⁴⁵-10⁴⁵, in 380T, but *not* on Tuesday evening or Wednesday morning. These changes are for October 18-20 only. After that the regular office hours schedule, posted on the course website, resumes. The SUMO tutoring is on Monday 6-10 in 381T.

After Midterm I

I expect to return the midterms to you on Wednesday in class. After that I will go over the most common errors.

Background Material

You should be familiar with and know how to use the two FTCs, chain and product rules, integration-by-parts and change-of-variables formulas. You may also encounter integrals like

$$\int te^{rt} dt, \quad \int \frac{1}{t(t+1)} dt, \quad \int e^{rt} \cos \omega t dt.$$

The last integral is computed in calculus by two integrations by parts, but it is far easier to use Euler's formula. If you encounter an integral you cannot compute quickly, you may instead want to replace it by an antiderivative and continue on, but be as specific as possible about your choices. For example, if you cannot compute the middle integral above, you may want to write some like:

$$\text{for } t > 0, \text{ let } F(t) = \int_1^t \frac{ds}{s(s+1)}$$

Types of Problems to Expect

- (1) *Solving First-Order ODEs*: find solutions of linear, separable, exact, and homogeneous (in the sense of Section 2.6) ODEs; check for exactness; determine correct constant, interval of existence, and/or square root for an IVP; sketch solution curves. Examples: 2.2:1-18, 2.4:1-8,13-21, 2.6:9-21,35-40.
- (2) *Autonomous Equations*: find equilibrium points, determine their type, show phase line, sketch solutions curves, and describe their limiting behavior. Examples: 2.9:15-28.
- (3) *Solving Second-Order Linear ODEs with Constant Coefficients*: find the characteristic roots and the general solution of a homogeneous ODE; find a particular solution of an inhomogeneous ODE; IVPs. Examples: 4.3:1-28; 4.5:1-47 (but choose your own method).
- (4) *Variation of Parameters*: given a nonzero solution of a linear homogeneous ODE, find another linearly independent solution; given two linearly independent solutions of the corresponding homogeneous ODE, find a particular solution of an inhomogeneous ODE. Examples: 4.1:14-18; 4.6:13,14.
- (5) *Higher-Order Equations*: find the characteristic roots and the general solution of a linear homogeneous ODE with constant coefficients.
- (6) *Existence and Uniqueness Theorem*: geometric implications; given a number of IVPs, determine to which ones the existence and uniqueness theorem applies; describe long-term behavior of solutions. Examples: 2.7:1-6, 2.7:25-32.
- (7) *Other*: solutions of ODEs and IVPs; direction fields and first-order ODEs; higher-order ODEs and first-order systems; Wronskian and linear independence; structure of solutions of linear ODEs. Examples: 2.1:8,17-20, 4.1:5-12.

Remarks: (1) You will not be asked to use a specific method to solve a second-order linear nonhomogeneous equation. Thus, if you feel comfortable using the method of undetermined coefficients of Section 4.5, you do not need to memorize the main formula involved in the integrating factor approach for second-order ODEs. However, you should know how to construct the general solution of a linear homogeneous ODE with constant coefficients from the roots of its characteristic polynomial.

(2) You will not need to memorize Kirchhoff's laws and similar things for either the midterm or the final. However, for the final exam, you should know that the velocity and the acceleration are the first and second derivatives of the displacement and that the concentration of a salt in water is its mass divided by the volume.
