## MAT 552 PROBLEM SET 5

Problems. This problem set completes the analytic proof of the Peter-Weyl Theorem. It is intended for those students with some background in Hilbert spaces and functional analysis.
Here is a quick reminder of the basics of complex Hilbert spaces including the statement of the spectral theorem. A complex Hilbert space is a Hermitian inner product space $(V, \beta)$ whose associated metric space is complete (all Cauchy sequences converge). For Hermitian inner product spaces $(V, \beta)$ and $(W, \gamma)$, a bounded linear transformation (resp. a compact linear transformation) is a $\mathbb{C}$-linear transformation,

$$
T: V \rightarrow W,
$$

sending closed balls in $(V, \beta)$ to bounded (resp. compact) subsets of $W$. The operator norm, $\|T\|_{\text {op }}$, of $T$ is the supremum of the $\gamma$-lengths of all elements in the $T$-image of the closed unit ball of $(V, \beta)$.
If the domain and target are complex Hilbert spaces, then the Closed Graph Theorem implies that $T$ is bounded if and only if the graph of $T$ is closed. In this case, there exists a unique bounded linear transformation,

$$
T^{*}:(W, \gamma) \rightarrow(V, \beta),
$$

such that for every $v \in V$ and for every $w \in W$,

$$
\gamma(w, T(v))=\beta\left(T^{*}(w), v\right) .
$$

This is the adjoint of $T$. Note that $\left\|T^{*}\right\|_{\text {op }}$ equals $\|T\|_{\text {op }}$.
The operation of adjoint makes $B((V, \beta),(V, \beta))$ and $B((W, \gamma),(W, \gamma))$ into (unital) $C^{*}$-algebras. Together with the operations sending $T$ to $T^{*} \circ T \in B((V, \beta),(V, \beta))$, resp. to $T \circ T^{*} \in B((W, \gamma),(W, \gamma))$, also $B((V, \beta),(W, \gamma))$ is a right Hilbert $C^{*}$ module, resp. left Hilbert $C^{*}$-module, for these respective $C^{*}$-algebras. An operator $T \in B((V, \beta),(V, \beta))$ is normal, resp. self-adjoint, if $T$ commutes with $T^{*}$, resp. if $T$ equals $T^{*}$.
By the Open Mapping Theorem, if $V$ and $W$ are complete, then every surjective bounded linear transformation is an open mapping. If $T$ is also injective, then $T$ is a homeomorphism whose inverse is also a bounded operator. Denote by $\operatorname{Inv}((V, \beta),(W, \gamma))$ the set of all bounded linear operators from $V$ to $W$ having a two-sided inverse that is also a bounded linear operator. Denote $\operatorname{Inv}((V, \beta),(V, \beta))$ by $\mathbf{G L}_{\mathbb{C}}(V, \beta)$; this is the group (and open subset) of invertible elements in the $C^{*}$-algebra $B((V, \beta),(V, \beta))$.
For every nonzero Hilbert space $(V, \beta)$ and for every bounded operator $T$ from $(V, \beta)$ to itself, the spectrum of $T$ is

$$
\operatorname{spec}(T):=\left\{\lambda \in \mathbb{C} \mid \lambda \operatorname{Id}_{V}-T \notin \mathbf{G L}_{\mathbb{C}}(V, \beta)\right\} .
$$

This is a compact subset of $\mathbb{C}$. The resolvent function,

$$
R(z ; T): \mathbb{C} \backslash \operatorname{spec}(T) \rightarrow \mathbf{G} \mathbf{L}_{\mathbb{C}}(V, \beta), \quad R(z ; T)=\left(T-z \operatorname{Id}_{V}\right)^{-1},
$$

is a holomorphic map to $B((V, \beta),(V, \beta))$. By Liouville's theorem, the spectrum is nonempty.
For every polynomial function in one variable $z$,

$$
f(z)=a_{0}+a_{1} z+a_{2} z^{2}+\cdots+a_{d} z^{d}
$$

the associated bounded operator $f(T)$ is defined by,

$$
f(T)=a_{0} \operatorname{Id}_{V}+a_{1} T+a_{2} T \circ T+\cdots+a_{d}(T \circ \cdots \circ T) .
$$

Every bounded continuous function $f$ on $\operatorname{spec}(T)$ is a uniform limit of a sequence of polynomial functions $f_{n}$. The operators $f_{n}(T)$ converge to a bounded operator $f(T)$ independent of the choice of convergent sequence of polynomials $\left(f_{n}\right)$. Denote $C^{o}(\operatorname{spec}(T), \mathbb{C})$ the $\mathbb{C}$-vector space of bounded continuous functions on $\operatorname{spec}(T)$. There is a well-defined $\mathbb{C}$-linear map,

$$
\operatorname{subs}_{T}: C^{0}(\operatorname{spec}(T), \mathbb{C}) \rightarrow B((V, \beta),(V, \beta))
$$

For every $f(z) \in C^{0}(\operatorname{spec}(T), \mathbb{C})$, denote by $E_{T, f}$ the kernel of $f(T)$ as a closed $\mathbb{C}$-linear subspace of $V$. For every closed subset $\Sigma \subset \operatorname{spec}(T)$, denote by $E_{T, \Sigma}$ the intersection of $E_{T, f}$ over all $f(z)$ that vanish on $\Sigma$.

Hypothesis 0.1. The operator $T \in B((V, \beta),(V, \beta))$ is self-adjoint.
Then the $\mathbb{C}$-linear map $\operatorname{subs}_{T}$ is a homomorphism of commutative, unital $C^{*}$ algebras, i.e., it sends function multiplication to composition, and it sends complex conjugation of functions to the adjoint operator.

Lemma 0.2 (Real spectrum, orthogonal eigenspaces). The spectrum of every selfadjoint operator $T$ is real. If $\Sigma, \Theta \subset \operatorname{spec}(T)$ are disjoint closed subsets, then $E_{T, \Sigma}$ and $E_{T, \Theta}$ are pairwise orthogonal closed subspaces.
Proof. For the polynomial $p_{\lambda}(z)=z-\lambda$ and associated norm-squared polynomial $\|p\|^{2}(z):=p_{\lambda}(z) \cdot \overline{p_{\lambda}(\bar{z})}$, observe

$$
p_{\lambda}(z) \cdot \overline{p_{\lambda}(\bar{z})}=\operatorname{Im}(\lambda)^{2}+(z-\operatorname{Re}(\lambda))^{2}
$$

Thus, for a self-adjoint operator $T$,

$$
\left(T-\lambda \operatorname{Id}_{V}\right) \circ\left(T-\lambda \operatorname{Id}_{V}\right)^{*}=\operatorname{Im}(\lambda)^{2} \operatorname{Id}_{V}+\left(T-\operatorname{Re}(\lambda) \operatorname{Id}_{V}\right)^{2} \geq \operatorname{Im}(\lambda)^{2} \operatorname{Id}_{V}
$$

Combined with the open mapping theorem, this implies that $T-\lambda \mathrm{Id}_{V}$ is invertible whenever $\operatorname{Im}(\lambda)$ is nonzero.

Next, by Urysohn's Lemma, there exist bounded, continuous, nonnegative realvalued functions $f(z)$ and $g(z)$ such that $f$ vanishes on $\Sigma$, such that $g$ vanishes on $\Theta$, and such that $f+g$ equals 1 . Thus, for every $v \in E_{T, \Sigma}$ and for every $w \in E_{T, \Theta}$,

$$
\begin{gathered}
\langle v, w\rangle=\langle(f(T)+g(T)) v, w\rangle=\langle f(T) v, w\rangle+\langle g(T) v, w\rangle= \\
\langle f(T) v, w\rangle+\langle v, g(T) w\rangle=\langle 0, w\rangle+\langle v, 0\rangle=0 .
\end{gathered}
$$

For every $v \in V$, denote by $\operatorname{subs}_{T, v}$ the following $\mathbb{C}$-linear map,

$$
\operatorname{subs}_{T, v}: C^{0}(\operatorname{spec}(T), \mathbb{C}) \rightarrow V, \quad f(z) \mapsto f(T) v
$$

The linear functional,

$$
\int_{\operatorname{spec}(T)}(-) d \pi_{T, v}: C^{0}(\operatorname{spec}(T), \mathbb{C}) \rightarrow \mathbb{C}, \quad f(z) \mapsto\left\langle\operatorname{subs}_{T, v}(f), v\right\rangle=\langle f(T) v, v\rangle
$$

defines a positive Borel measure $d \pi_{T, v}$ on $\operatorname{spec}(T)$ that is even a Radon measure. Denote by $L^{2}\left(\operatorname{spec}(T), d \pi_{T, v}\right)$ the corresponding Lebesgue space of square-integrable functions on $\operatorname{spec}(T)$ with respect to $d \pi_{T, v}$.

Theorem 0.3 (Spectral Theorem for Self-Adjoint Operators). For every nonzero complex Hilbert space $(V, \beta)$, for every bounded, self-adjoint operator $T$ on $(V, \beta)$, for every $v \in V$, the $\mathbb{C}$-linear map subs $s_{T, v}$ extends to an isometric embedding of Hilbert spaces,

$$
\operatorname{subs}_{T, v}: L^{2}\left(\operatorname{spec}(T), d \pi_{T, v}\right) \rightarrow V,
$$

whose image is the smallest closed, $T$-stable subspace of $V$ containing $v$.
Theorem 0.4 (Spectral Theorem for Self-Adjoint Compact Operators). Further, $T$ is compact if and only if $\operatorname{spec}(T) \backslash\{0\}$ contains no accumulation points, if the eigenspace of each $\lambda \in \operatorname{spec}(T) \backslash\{0\}$ has finite dimension, and, together with $\operatorname{Ker}(T)$, these eigenspaces span a dense subspace of $V$.
Corollary 0.5. A bounded, self-adjoint operator on a nonzero complex Hilbert space is a scalar multiple of the identity if and only if the spectrum is a singleton set.

Proof. If $T$ equals $\lambda \operatorname{Id}_{V}$ for a real number $\lambda$, then $\operatorname{spec}(T)$ equals $\{\lambda\}$. Conversely, assume that $\operatorname{spec}(T)$ equals $\{\lambda\}$. For every nonzero vector $v \in V$, since $\lambda-z$ restricts to zero on $\operatorname{spec}(T)=\{\lambda\}$, the restriction of this polynomial in $L^{2}\left(\operatorname{spec}(T), d \pi_{T, v}\right)$ is zero. Thus, $\lambda \operatorname{Id}_{V}-T$ acts as the zero operator on $v$, i.e., $T(v)=\lambda v$. Since this holds for every $v \in V$, the operator $T$ equals $\lambda \operatorname{Id}_{V}$.

Problem 1. (Schur's Lemma, Part 1.) For a Lie group $G$, a unitary representation in a complex Hilbert space $(V, \beta)$ is a continuous group homomorphism to the group of unitary (i.e., norm-preserving) $\mathbb{C}$-linear automorphisms of $(V, \beta)$ with its norm topology,

$$
\rho: G \rightarrow U(V, \beta) .
$$

This representation is irreducible if the only closed, $\rho(G)$-invariant subspaces of $V$ are $V$ and $\{0\}$.
(a) For unitary $G$-representations $(V, \beta, \rho)$ and $(W, \gamma, \sigma)$, for every bounded morphism of $G$-representations,

$$
S: V \rightarrow W, \quad S \circ \rho_{g}=\sigma_{g} \circ S, \forall g \in G
$$

prove that also the adjoint $S^{*}$ is a bounded morphism of $G$-representations.
(b) Also prove that the kernel of $S$ and the kernel of $S^{*}$ are closed subrepresentations. Similarly, the orthogonal complements of $\operatorname{Ker}\left(S^{*}\right)$ and $\operatorname{Ker}(S)$ are closed subrepresentations. These orthogonal complements equal the closures of the images of $S$ and $S^{*}$.
(c) Check that $T:=S^{*} \circ S$ is a bounded, self-adjoint operator on $(V, \beta)$ that is a morphism of $G$-representations.
(d) Now assume that $(V, \beta, \rho)$ and $(W, \gamma, \sigma)$ are both irreducible unitary representations. If $T$ is surjective, conclude that $S^{*}$ is an isomorphism, and thus also the
adjoint $S=\left(S^{*}\right)^{*}$ is an isomorphism. Thus, to prove Schur's Lemma for unitary representations, it suffices to prove that every bounded, self-adjoint morphism from an irreducible unitary representation ( $V, \rho$ ) to itself equals a multiple of the identity operator.

Problem 2. (Schur's Lemma, Part 2.) Let ( $V, \beta, \rho$ ) be an irreducible unitary $G$-representation. Let $T$ be a bounded, self-adjoint operator of $(V, \beta)$ that is a morphism of $G$-representations.
(a) Prove that every element of $\operatorname{subs}_{T}\left(C^{0}(\operatorname{spec}(T), \mathbb{C})\right)$ is a bounded operator on $(V, \beta)$ that is a self-morphism of unitary $G$-representations.
(b) For a nonzero vector $v \in V$, assume by way of contradiction that the measure space $\left(\operatorname{spec}(T), d \pi_{T, v}\right)$ is not a singular measure supported at a single point. Use Urysohn's Lemma to find continuous functions $f(z), g(z) \in C^{0}(\operatorname{spec}(T), \mathbb{C})$ with $f(z) \cdot g(z)=0$ and with images in $L^{2}\left(\operatorname{spec}(T), d \pi_{T, v}\right)$ that are each nonzero. Since $f(T) \circ g(T)$ and $g(T) \circ f(T)$ equal 0 , conclude that at least one of $f(T)$ or $g(T)$ has nonzero kernel, say $f(T)$. On the other hand, since $f(T) v$ is nonzero by the spectral theorem, conclude a contradiction. Altogether, conclude that for every nonzero vector $v \in V$, the measure space $\left(\operatorname{spec}(T), d \pi_{T, v}\right)$ is a singular metric supported at a single point $\lambda_{v}$. Repeat the proof of the corollary to conclude that $T(v)$ equals $\lambda_{v} \cdot v$.
(c) For a $\mathbb{C}$-linear operator on a $\mathbb{C}$-vector space $V$, if every vector is an eigenvector for some eigenvalue, conclude that the operator is a scalar multiple of the identity. Thus, for $T$ as above, conclude that there exists $\lambda \in \mathbb{R}$ with $T=\lambda \operatorname{Id}_{V}$.
Problem 3. (Eigenspaces of convolution operators.) Assume now that $G$ is a compact (real) Lie group with normalized Haar measure $d \mathrm{vol}_{G}$. For every $g \in G$, define

$$
\begin{aligned}
& \lambda_{g}: L^{2}\left(G, d \operatorname{vol}_{G}\right) \rightarrow L^{2}\left(G, d \mathrm{vol}_{G}\right), \quad\left(\lambda_{g} u\right)(h):=u\left(g^{-1} h\right), \\
& \rho_{g}: L^{2}\left(G, d \operatorname{vol}_{G}\right) \rightarrow L^{2}\left(G, d \mathrm{vol}_{G}\right), \quad\left(\lambda_{g} u\right)(h):=u\left(h g^{-1}\right),
\end{aligned}
$$

For all continuous functions $u, v \in C^{0}(G, \mathbb{C})$, define the convolution function $u * v$ on $G$ by

$$
u * v(h)=\int_{g \in G} u(g)\left(\lambda_{g} v\right)(h) d \operatorname{vol}_{G}(g)=\int_{g \in G}\left(\rho_{g} u\right)(h) v(g) d \operatorname{vol}_{G}(g) .
$$

(a) Prove that $\lambda_{g}$ and $\rho_{g}$ are isometries. Prove that these define left, resp. right, unitary representations $\lambda: G \rightarrow U\left(L^{2}\left(G, d \mathrm{vol}_{G}\right)\right)$ and $\rho: G^{\mathrm{opp}} \rightarrow U\left(L^{2}\left(G, d \mathrm{vol}_{G}\right)\right)$. Prove that these commute with one another, $\lambda_{g}\left(\rho_{h} u\right)=\rho_{h}\left(\lambda_{g} u\right)$.
(b) Prove that the $L^{\infty}$ norm of $u * v$ is bounded above by $\|u\|_{2} \cdot\|v\|_{2}$. (Hint. Use that the group inversion preserves the Haar measure. Thus the $L^{2}$-norm of $g \mapsto \lambda_{g} v(h)$ equals the $L^{2}$-norm of $v$.)
(c) Since $G$ is a finite measure space, $L^{\infty}$ is a subspace of $L^{2}$. Conclude that convolution extends to a continuous $\mathbb{C}$-bilinear operation,
$*: L^{2}\left(G, d \mathrm{vol}_{G}\right) \times L^{2}\left(G, d \mathrm{vol}_{G}\right) \rightarrow L^{2}\left(G, d \mathrm{vol}_{G}\right),\|u * v\|_{2} \leq\|u * v\|_{\infty} \leq\|u\|_{2} \cdot\|v\|_{2}$.
In particular, for every $w \in L^{2}\left(G, d \mathrm{vol}_{G}\right)$, deduce that the following operators are bounded operators,

$$
\lambda_{w}: L^{2}\left(G, d \mathrm{vol}_{G}\right) \rightarrow \underset{4}{L^{2}\left(G, d \operatorname{vol}_{G}\right), \quad v \mapsto w * v,}
$$

$$
\rho_{w}: L^{2}\left(G, d \operatorname{vol}_{G}\right) \rightarrow L^{2}\left(G, d \operatorname{vol}_{G}\right), \quad u \mapsto u * w
$$

For the "heuristic" Dirac delta function $\delta_{g}$ of $g \in G$, this gives identities,

$$
\lambda_{g}(v)=\lambda_{\delta_{g}}(v), \quad \rho_{g}(u)=\rho_{\delta_{g}}(u)
$$

(d) For every $u, v, w \in L^{2}\left(G, d \operatorname{vol}_{G}\right)$ and every $g \in G$, check the following identities,

$$
\begin{aligned}
u * 1_{G}= & 1_{G} * u=\left(\int_{g \in G} u(g) d \operatorname{vol}_{G}(g)\right) 1_{G}, \\
& (u * v) * w=u *(v * w) \\
\lambda_{g}(v * w)= & \left(\lambda_{g}(v)\right) * w, \quad \rho_{g}(u * v)=u *\left(\rho_{g}(v)\right), \\
\lambda_{u}(v * w)= & \left(\lambda_{u}(v)\right) * w, \quad \rho_{w}(u * v)=u *\left(\rho_{w}(v)\right) .
\end{aligned}
$$

(e) For every $w \in L^{2}\left(G, d \operatorname{vol}_{G}\right)$, define $\widetilde{w} \in L^{2}\left(G, d \operatorname{vol}_{G}\right)$ by

$$
\widetilde{w}(g)=\overline{w\left(g^{-1}\right)}
$$

so that

$$
u * \widetilde{w}(h)=\left\langle u, \lambda_{h} w\right\rangle_{G} .
$$

Prove that the adjoint of $\lambda_{w}$ equals $\lambda_{\widetilde{w}}$, and prove that the adjoint of $\rho_{w}$ equals $\rho_{\widetilde{w}}$. In particular, conclude that $\lambda_{w}$, resp. $\rho_{w}$, is self-adjoint if and only if $\widetilde{w}$ equals $w$, e.g., $\rho_{\chi}$ is self-adjoint for the (trace) character $\chi$ of every finite-dimensional $\mathbb{C}$-linear representation of $G$.
(f) Read about Hilbert-Schmidt operators. Conclude that $\lambda_{w}$ and $\rho_{w}$ are HilbertSchmidt operator, thus they are compact. When $\widetilde{w}$ equals $w$, conclude that these are compact self-adjoint operators. Since $\lambda_{u}\left(\rho_{w}(v)\right)$ equals $\rho_{w}\left(\lambda_{u}(v)\right)$, conclude that the eigenspaces of $\rho_{w}$, resp. of $\lambda_{w}$, are left $G$-subrepresentations of $L^{2}\left(G, d \mathrm{vol}_{G}\right)$, resp. right $G$-subrepresentations of $L^{2}\left(G, d \mathrm{vol}_{G}\right)$. Since the eigenspaces of a compact operator for nonzero eigenvalues have finite dimension, conclude that these eigenspaces for $\rho_{w}$, resp. for $\lambda_{w}$, are direct sums of finitely many irreducible left, resp. right, $G$-subrepresentations that have finite dimension.
(g) A sequence $\left(w_{n}\right)_{n \geq 0}$ of continuous, nonnegative real-valued functions on $G$ is a balanced Dirac sequence if each $\widetilde{w_{n}}$ equals $w_{n}$, if each $\int_{g} w_{n}(g) d \operatorname{vol}_{G}(g)$ equals 1 , and if for every $\epsilon>0$ and every open neighborhood of $e \in G$, for all $n \gg 0$, we have $\left|w_{n}(g)\right|<\epsilon$ for all $g$ outside the open neighborhood. Prove that there exists a balanced Dirac sequence.
(h) For every $v \in C^{0}(G, \mathbb{C})$, prove that $\rho_{w_{n}}(v)$ converges uniformly to $v$ on $G$, and thus converges to $v$ in $L^{2}\left(G, d \mathrm{vol}_{G}\right)$. For every $u \in L^{2}\left(G, d \mathrm{vol}_{G}\right)$, use selfadjointness of $\rho_{w_{n}}$ to prove that

$$
\lim _{n \rightarrow \infty}\left\langle\rho_{w_{n}}(u), v\right\rangle_{L^{2}}=\langle u, v\rangle
$$

Since the continuous functions are dense in $L^{2}\left(G, d \mathrm{vol}_{G}\right)$, prove that this holds for every $v \in L^{2}\left(G, d \operatorname{vol}_{G}\right)$, i.e., $\rho_{w_{n}}(u)$ converges weakly to $u$. In particular, if $\rho_{w_{n}}(u)$ equals 0 for all $n \gg 0$, conclude that also $u$ equals 0 .
(i) Conclude that for every nonzero $u \in L^{2}\left(G, d \operatorname{vol}_{G}\right)$, for all $n \gg 0$, the element $u$ is not in $\operatorname{Ker}\left(\rho_{w_{n}}\right)$. Thus, $u$ has nonzero orthogonal projection to at least one of the eigenspaces of $\rho_{w_{n}}$ with nonzero eigenvalue. Since this is a direct sum of finitely many irreducible (left) $G$-subrepresentations, conclude that $u$ has nonzero projection to at least one irreducible (left) $G$-subrepresentation of finite dimension.

Thus, the sum in $L^{2}\left(G, d \mathrm{vol}_{G}\right)$ of all irreducible (left) $G$-subrepresentations of finite dimension is dense in $L^{2}\left(G, d \mathrm{vol}_{G}\right)$. This completes the proof of surjectivity in the Peter-Weyl Theorem.

Problem 4. (Irreducible unitary representations of compact groups have finite dimension.) Let $G$ be a compact (real) Lie group. Let $(V, \beta)$ be a nonzero complex Hilbert space, and let $\rho: G \rightarrow U(V, \beta)$ be a unitary representation that is irreducible. For any nonzero vector $v \in V$, and for the orthogonal projection to the span of $v$,

$$
\operatorname{proj}_{v}: V \rightarrow \operatorname{span}(v) \subseteq V,
$$

consider the $\mathbb{C}$-linear operator on $V$,

$$
T=\int_{g \in G} \rho_{g} \circ \operatorname{proj}_{v} \circ \rho_{g}^{-1} d \operatorname{vol}_{G}(g)
$$

(a) Prove that $T$ is a bounded linear operator that is a morphism of $G$-representations. By Schur's Lemma, conclude that $T$ equals $\lambda \operatorname{Id}_{V}$ for some real number $\lambda$.
(b) Compute that

$$
\begin{gathered}
\langle T(v), v\rangle=\int_{g \in G}\left\langle\operatorname{proj}_{v} \circ \rho_{g}^{-1}(v), \rho_{g}^{-1}(v)\right\rangle d \operatorname{vol}_{G}(g)= \\
\int_{g \in G}\left\langle\operatorname{proj}_{v} \circ \rho_{g}^{-1}(v), \operatorname{proj}_{v} \circ \rho_{g}^{-1}(v)\right\rangle d \operatorname{vol}_{G}(t) .
\end{gathered}
$$

Prove that the function $g \mapsto\left\langle\operatorname{proj}_{v} \circ \rho_{g}^{-1}(v), \operatorname{proj}_{v} \circ \rho_{g}^{-1}(f)\right\rangle$ is continuous and nonzero at $g=e$. Conclude that the integral is a positive real number, and thus also $\lambda$ is positive.
(c) Since $T$ is defined as a limit of Riemann sums, prove that $T$ is in the closure of the finite-rank operators, i.e., $T$ is a compact operator. Thus the identity operator on $V$ is a compact operator. Conclude that $V$ has finite dimension. Thus, every irreducible (left) unitary $G$-representation has finite dimension, and hence occurs in the Peter-Weyl Theorem.
Problem 5. (Compact Lie groups have faithful representations of finite dimension.) Let $G$ be a compact (real) Lie group. Let $W \subset L^{2}\left(G, d \mathrm{vol}_{G}\right)$ be a finite dimensional subspace containing a system of coordinate functions of $G$ relative to an embedding of $G$ as a submanifold of the real manifold $\mathbb{C}^{n}$. Use the previous problems to prove that there exists a unitary representation $(V, \beta, \rho)$ that is a finite direct sum of irreducible unitary representations such that $W$ is contained in the image of $V^{\vee} \otimes_{\mathbb{C}} V$. Since the span of the matrix entries of $\rho$ contain coordinate functions, conclude that $\rho$ is injective. Thus, every compact (real) Lie group has a faithful (unitary) representation of finite dimension.
