MATH 125   Solutions to Second Midterm, Vers. 1

1. For each of the functions $f(x)$ given below, find $f'(x)$).

(a) 4 points $f(x) = x^5 + 5x^4 + 2x^2 + 9$

Solution:
$$f'(x) = 5x^4 + 20x^3 + 4x$$

(b) 4 points $f(x) = x^6 e^x$

Solution: This requires the product rule. Recall that the derivative of e^x is e^x.
$$f'(x) = 6x^5 e^x + x^6 e^x$$

(c) 4 points $f(x) = \dfrac{3x^2 + 5}{x^3 + 2\tan x}$

Solution: Using the quotient rule,
$$\frac{6x(x^3 + 2\tan x) - (3x^2 + 5)(x^2 + 2\sec^2 x)}{(x^3 + 2\tan x)^2}$$

There is little point in trying to simplify this.

2. Compute each of the following derivatives as indicated:

(a) 4 points $\dfrac{d}{d\theta}\left[\cos\left(\dfrac{\pi}{180}\theta\right)\right]$

Solution: This is just the derivative of the $\cos\theta$, when θ is in degrees. Using the chain rule, we get
$$-\frac{\pi}{180}\sin\left(\frac{\pi}{180}\theta\right)$$

(b) 4 points $\dfrac{d}{du}[\sin(3u)\sin(2u)]$

Solution: Use the product rule to get
$$\left(\frac{d}{du}\sin(3u)\right)\sin(2u) + \sin(3u)\left(\frac{d}{du}\sin(2u)\right)$$

and then use the chain rule to get the answer, which is
$$3\cos(3u)\sin(2u) + 2\sin(3u)\cos(2u).$$

(c) $\boxed{4 \text{ points}}$ $\dfrac{d}{dt}\left[\dfrac{t}{3} - \dfrac{3}{t}\right]$

Solution: If you rewrite this as $\frac{1}{3}t - 3t^{-1}$, it is clear the derivative is $\dfrac{1}{3} + 3t^{-2}$

3. $\boxed{8 \text{ points}}$ Write a limit that represents the slope of the graph

$$y = \begin{cases} 8 + x\ln|x| & x \neq 0 \\ 8 & x = 0 \end{cases}$$

at $x = 0$. You **do not need to evaluate the limit.**

Solution: To do this, we need to remember the definition of the derivative, which is $f'(a) = \lim\limits_{h\to 0} \dfrac{f(a+h) - f(a)}{h}$. In the current case, $a = 0$, and notice that $f(0) = 8$, so we have

$$\lim_{h\to 0} \frac{f(h) - f(0)}{h} = \lim_{h\to 0} \frac{(8 + h\ln|h|) - 8}{h}$$

This simplifies to

$$\lim_{h\to 0} \frac{h\ln|h|}{h} = \lim_{h\to 0} \ln|h| = -\infty,$$

although it wasn't required for you to do this.

4. At right is the graph of **the derivative** f' of a function.

(a) $\boxed{4 \text{ points}}$ List all values of x with $-3 \leq x \leq 4$ where $f(x)$ has a local maximum.

Solution: A local maximum for $f(x)$ will occur where $f'(x)$ changes from positive to negative. This happens at $x = 0$.

(b) $\boxed{4 \text{ points}}$ At $x = -1$, is $f(x)$ concave up, concave down, or neither?

Solution: We know that a function is concave up when its second derivative is positive, and concave down when f'' is negative. The graph shows $f'(x)$, which is decreasing near $x = -1$. That means the derivative of $f'(x)$ is negative near $x = -1$, so $f''(-1) < 0$. Hence $f(x)$ is concave down at $x = -1$.
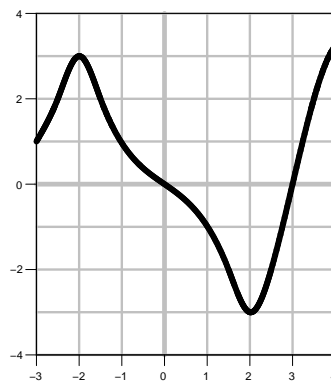

5. $\boxed{16 \text{ points}}$ For each of the 4 functions graphed in the left column, find the corresponding derivative function among any of the 8 choices on the right (not just on the same row) and put its letter in the corresponding box.

$\boxed{\textbf{D}}$

6. Let $f(x) = x\,e^{-4x}$.

   (a) $\boxed{3 \text{ points}}$ Calculate $f'(x)$

   Solution: We use the product rule and the chain rule:
   $$f'(x) = e^{-4x} - 4x\,e^{-4x}$$

   (b) $\boxed{3 \text{ points}}$ Calculate $f''(x)$?

   Solution: Taking the derivative of the above gives
   $$f''(x) = -4e^{-4x} - 4e^{-4x} + 16x\,e^{-4x}$$
   which simplifies to
   $$16x\,e^{-4x} - 8e^{-4x}$$

   (c) $\boxed{4 \text{ points}}$ For what values of x is $f(x)$ increasing?

   Solution: To answer this, we need to know when $f'(x) > 0$, that is, where
   $$e^{-4x} - 4x\,e^{-4x} > 0$$
   Factoring out the exponential term gives $e^{-4x}(1 - 4x) > 0$, and since e^{-4x} is always positive, we only need ask where $1 - 4 > 0$. This happens for
   $$x < \frac{1}{4}.$$

   (d) $\boxed{4 \text{ points}}$ For what values of x is $f(x)$ concave down?

   Solution: We need to know when $f''(x) < 0$, so factor $f''(x)$ as
   $$8e^{-4x}(2x - 1).$$
   As before, we can ignore the exponential term, since it is always positive, and we see that $f''(x) < 0$ when $x < 1/2$.

7. 10 points Write the equation of the line tangent to the curve

$$y = 3x^4 - 2x + \sqrt{x} \qquad \text{at } x = 1$$

Solution: To write the equation of a line, we need a point and a slope. Since the line is tangent to the curve at $x = 1$, it contains the point $(1, f(1)) = (1, 2)$.

To get the slope, we calculate $f'(1)$. Taking the derivative gives

$$f'(x) = 12x^3 - 2 + \frac{1}{2}x^{-1/2},$$

so $f'(1) = 12 - 2 + \frac{1}{2} = \frac{21}{2}$. Hence the line is

$$y - 2 = \frac{21}{2}(x - 1), \quad \text{or, equivalently,} \quad y = \frac{21}{2}x - \frac{17}{2}$$

8. 10 points A ladder 16 feet long rests against a vertical wall. Let θ be the angle between the top of the ladder and the wall, and let ℓ be the distance from the bottom of the ladder to the wall. If the bottom of the ladder slides away from the wall, how fast does ℓ change with respect to θ when $\theta = \frac{\pi}{6}$?

Solution: Since the ladder forms a right triangle with the wall, we have $\ell = 16 \sin \theta$. The rate of change of ℓ with respect to θ is $\frac{d\ell}{d\theta}$, which is $16 \cos \theta$. We want its value when $\theta = \frac{\pi}{6}$, so that is

$$16 \cos \left(\frac{\pi}{6} \right) = 16 \cdot \frac{\sqrt{3}}{2} = 8\sqrt{3}$$
