Matings: a quick guide

Mating allows us to construct a rational map by gluing together two polynomials:

Let $f:\widehat{\mathbb{C}}\to\widehat{\mathbb{C}}$ be a rational map.

- The Julia set *J*(*f*) is the closure of the set of repelling periodic points of *f*.
- The Fatou set F(f) is $\widehat{\mathbb{C}} \setminus J(f)$.

Let $f:\widehat{\mathbb{C}}\to\widehat{\mathbb{C}}$ be a rational map.

- The Julia set *J*(*f*) is the closure of the set of repelling periodic points of *f*.
- The Fatou set F(f) is $\widehat{\mathbb{C}} \setminus J(f)$.
- If f is a polynomial
 - The point ∞ is a superattracting fixed point.
 - The filled Julia set is $K(f) = \{z \in \widehat{\mathbb{C}} \mid f^{\circ n}(z) \nrightarrow \infty\}$, so that $J(f) = \partial K(f)$

•
$$R_{\theta} = \phi^{-1}\{re^{2\pi i\theta} \mid r \in (1,\infty)\}$$
 is called the external ray of angle θ .

• If J(f) is locally connected, the landing point $\gamma(\theta) = \lim_{r \to 1} \phi^{-1}(re^{2\pi i\theta})$ exists for all θ and belongs to J(f).

• We have the identities $f(R_{\theta}) = R_{d\theta}$ and $f(\gamma(\theta)) = \gamma(d\theta)$.

For i = 1, 2, let f_i be monic degree d polynomials. Define $\widetilde{\mathbb{C}} = \mathbb{C} \cup \{\infty \cdot e^{2\pi i s} \mid s \in \mathbb{R}/\mathbb{Z}\}.$

Thurston's Theorem

Let $F: \Sigma \to \Sigma$ and $\widehat{F}: \widehat{\Sigma} \to \widehat{\Sigma}$ be postcritically finite orientation-preserving branched self-coverings of topological 2-spheres. An equivalence is given by a pair of orientation-preserving homeomorphisms (Φ, Ψ) from Σ to $\widehat{\Sigma}$ such that

•
$$\Phi|_{P_F} = \Psi|_{P_F}$$

•
$$\Phi \circ F = \widehat{F} \circ \Psi$$

• Φ and Ψ are isotopic via a family of homeomorphisms $t \mapsto \Phi_t$ which is constant on P_F .

Thurston's Theorem

Let $F: \Sigma \to \Sigma$ and $\widehat{F}: \widehat{\Sigma} \to \widehat{\Sigma}$ be postcritically finite orientation-preserving branched self-coverings of topological 2-spheres. An equivalence is given by a pair of orientation-preserving homeomorphisms (Φ, Ψ) from Σ to $\widehat{\Sigma}$ such that

•
$$\Phi|_{P_F} = \Psi|_{P_F}$$

•
$$\Phi \circ F = \widehat{F} \circ \Psi$$

• Φ and Ψ are isotopic via a family of homeomorphisms $t \mapsto \Phi_t$ which is constant on P_F .

Theorem (Thurston)

Let $F: \Sigma \to \Sigma$ be a postcritically finite branched cover with hyperbolic orbifold. Then F is equivalent to a rational map if and only if F has no Thurston obstructions. This rational map is unique up to Möbius transformation.

We say f_1 and f_2 are mateable if $f_1 \perp \!\!\!\perp f_2$ is equivalent to a rational map on $\widehat{\mathbb{C}}$.

Tom Sharland (Stony Brook University)

Thurston obstructions

Let $F: S^2 \to S^2$ be a branched covering and $\Gamma = \{\gamma_1, \dots, \gamma_n\}$ a multicurve in $S^2 \setminus P_F$.

Definition

The Thurston linear transformation $F_{\Gamma} \colon \mathbb{R}^{\Gamma} \to \mathbb{R}^{\Gamma}$ is defined by

$$F_{\Gamma}(\gamma) = \sum_{\gamma' \subset F^{-1}(\gamma)} \frac{1}{\deg(F \colon \gamma' \to \gamma)} [\gamma']_{\Gamma}$$

where $[\gamma']_{\Gamma} \in \Gamma$ is isotopic to γ' . Γ is a Thurston obstruction if its leading eigenvalue is greater than or equal to 1.

< ロト < 同ト < ヨト < ヨト

Thurston obstructions

Let $F: S^2 \to S^2$ be a branched covering and $\Gamma = \{\gamma_1, \dots, \gamma_n\}$ a multicurve in $S^2 \setminus P_F$.

Definition

The Thurston linear transformation $F_{\Gamma} \colon \mathbb{R}^{\Gamma} \to \mathbb{R}^{\Gamma}$ is defined by

$$F_{\Gamma}(\gamma) = \sum_{\gamma' \subset F^{-1}(\gamma)} \frac{1}{\deg(F \colon \gamma' \to \gamma)} [\gamma']_{\Gamma}$$

where $[\gamma']_{\Gamma} \in \Gamma$ is isotopic to γ' . Γ is a Thurston obstruction if its leading eigenvalue is greater than or equal to 1.

Definition

A multicurve is called a Levy cycle if for i = 1, 2, ..., n, the curve γ_{i-1} is homotopic (rel P_F) to a component γ'_{i-1} of $F^{-1}(\gamma_i)$ and the map $F: \gamma'_i \to \gamma_i$ is a homeomorphism

Quadratic Case

The quadratic (or bicritical) case is reasonably well understood:

Theorem (Rees, Shishikura, Tan)

In the bicritical case, if f_1 and f_2 do not lie in conjugate limbs of \mathcal{M} , then $K_1 \perp \!\!\!\perp K_2$ is homeomorphic to S^2 and we can give this sphere a unique conformal structure to make $f_1 \perp \!\!\!\perp f_2$ a holomorphic degree drational map.

10/27

Quadratic Case

The quadratic (or bicritical) case is reasonably well understood:

Theorem (Rees, Shishikura, Tan)

In the bicritical case, if f_1 and f_2 do not lie in conjugate limbs of \mathcal{M} , then $K_1 \perp \!\!\!\perp K_2$ is homeomorphic to S^2 and we can give this sphere a unique conformal structure to make $f_1 \perp \!\!\!\perp f_2$ a holomorphic degree drational map.

 Essentially, this says that in the quadratic case, the quotient is a sphere if and only if the resulting map is equivalent to a rational map. All obstructions are Levy cycles.

- Essentially, this says that in the quadratic case, the quotient is a sphere if and only if the resulting map is equivalent to a rational map. All obstructions are Levy cycles.
- The mating is obstructed if and only if the two α -fixed points belong to the same ray class.

10/27

Other obstructions

However, there exist other obstructions in higher degrees: Consider the following

Both polynomials are in S_3 . The quotient is a sphere, but the mating is not a rational map.

Stony Brook University

11/27

There is a close link between Levy cycles and loops of external rays in the formal mating.

Theorem (Tan 1992, Shishikura-Tan 2000)

Let $F = f \perp \!\!\!\perp g$.

- Each Levy cycle Γ for F corresponds to a unique periodic cycle of ray classes (the "limit set"). In particular, if Γ is not a degenerate Levy cycle, then each ray class contains a closed loop.
- If a periodic ray class contains a closed loop then each boundary curve of a tubular neighbourhood generates a Levy cycle.

Limbs in \mathcal{S}_1

Like the Mandelbrot set, S_1 has a main hyperbolic component \mathcal{H}_0 . Its centre is $z \mapsto z^3$.

Tom Sharland (Stony Brook University)

Limbs in \mathcal{S}_1

Like the Mandelbrot set, S_1 has a main hyperbolic component \mathcal{H}_0 . Its centre is $z \mapsto z^3$.

Attached to this component are various limbs.

Limbs in \mathcal{S}_1

Like the Mandelbrot set, S_1 has a main hyperbolic component \mathcal{H}_0 . Its centre is $z \mapsto z^3$.

Attached to this component are various limbs.

Limbs are characterised by the existence of α -periodic cycles. We will look at an example, one of the $\frac{2}{3}$ -limbs in S_1 .

Denote by U the Fatou component containing the fixed critical point a. Maps in the $\frac{p}{q}$ -limb have a "dynamical limb" containing the free critical point attached to the landing point of the internal ray of angle $\frac{p}{a}$ in U.

Denote by U the Fatou component containing the fixed critical point a. Maps in the $\frac{p}{q}$ -limb have a "dynamical limb" containing the free critical point attached to the landing point of the internal ray of angle $\frac{p}{a}$ in U.

This gives us a distinguished periodic cycle which we call the α -periodic cycle. Furthermore, the angles of the external rays landing at this periodic cycle persist in the limb.

15/27

Let f_1 , f_2 be postcritically finite polynomials in S_1 with filled Julia sets K_1 and K_2 respectively.

Question

When is the quotient space $K_1 \perp L K_2$ a sphere (when are f_1 and f_2 topologically mateable)?

< ロト < 同ト < ヨト < ヨト

The (formal) mating of two maps in \mathcal{S}_1 is a cubic branched covering with two fixed critical points.

The (formal) mating of two maps in S_1 is a cubic branched covering with two fixed critical points.

Suppose Γ is an irreducible obstruction which is not a removable Levy cycle. Then there is a disk component D for which $F^{-1}(D)$ contains a non-disk component. We have a dichotomy:

The (formal) mating of two maps in S_1 is a cubic branched covering with two fixed critical points.

Suppose Γ is an irreducible obstruction which is not a removable Levy cycle. Then there is a disk component D for which $F^{-1}(D)$ contains a non-disk component. We have a dichotomy:

- D contains a fixed critical point.
- 2 D contains both "free" critical values.

Stony Brook

The (formal) mating of two maps in S_1 is a cubic branched covering with two fixed critical points.

Suppose Γ is an irreducible obstruction which is not a removable Levy cycle. Then there is a disk component D for which $F^{-1}(D)$ contains a non-disk component. We have a dichotomy:

- D contains a fixed critical point.
- ② D contains both "free" critical values.

The first case is a "Newton-like" case, the second a "quadratic-like" case. We will show in both cases that Γ must contain a Levy cycle.

This case is similar to the case of cubic Newton maps (Tan '97).

This case is similar to the case of cubic Newton maps (Tan '97).

Let Γ be an irreducible obstruction for F. Suppose D is a disk component of $S^2 \setminus \Gamma$ and that

- $F^{-1}(D)$ contains a non-disk component U
- D contains a fixed critical point c.

This case is similar to the case of cubic Newton maps (Tan '97).

Let Γ be an irreducible obstruction for F. Suppose D is a disk component of $S^2\setminus\Gamma$ and that

- $F^{-1}(D)$ contains a non-disk component U
- D contains a fixed critical point c.

In particular, one component U of $F^{-1}(D)$ must contain c, and so is isotopically contained in D.

Case 2: Quadratic-like

This case has much in common with the case of quadratic matings (Rees-Shishikura-Tan Theorem).

Let Γ be an irreducible obstruction for F. Suppose D is a disk component of $S^2 \setminus \Gamma$ and that

- $F^{-1}(D)$ contains a non-disk component U
- D contains both free critical values.

By a generalised "Rees' Lemma", the set of disk components of $S^2 \setminus \Gamma$ form a sequence

$$D=D_1,D_2,\ldots,D_p\ldots$$

Case 2: Quadratic-like

This case has much in common with the case of quadratic matings (Rees-Shishikura-Tan Theorem).

Let Γ be an irreducible obstruction for F. Suppose D is a disk component of $S^2 \setminus \Gamma$ and that

- $F^{-1}(D)$ contains a non-disk component U
- D contains both free critical values.

By a generalised "Rees' Lemma", the set of disk components of $S^2 \setminus \Gamma$ form a sequence

 $D = D_1, D_2, \dots, D_p \dots$ and we can construct a Levy cycle by showing every curve has 3 pre-images.

Outline of proof (in progress)

Using the previous results, we argue (possibly?) as follows. There are parallels with the proof in the quadratic case.

Using the previous results, we argue (possibly?) as follows. There are parallels with the proof in the quadratic case.

- Every obstruction is a Levy cycle, and so has an associated limit set which is a collection of ray classes.
 - These ray classes contain loops
 - These ray classes contain periodic points of J_1 and J_2 .

Using the previous results, we argue (possibly?) as follows. There are parallels with the proof in the quadratic case.

- Every obstruction is a Levy cycle, and so has an associated limit set which is a collection of ray classes.
 - These ray classes contain loops
 - These ray classes contain periodic points of J_1 and J_2 .
- We then show that
 - The ray classes are just loops (and have no endpoints)
 - The periodic points are precisely the points in α_1 and α_2 .

 - The ray classes are just loops (and have no endpoints)
 - The periodic points are precisely the points in α_1 and α_2 .

Remarks

- The result generalises to the case where the polynomials are of degree d and have a fixed point of degree d - 1 (see Roesch '07).
- Presumably something similar can be done in the case where the polynomials have two critical points and one is fixed.
