## PROBLEM SET 3

1. A function is called simple if it only takes on finite number of different values. If $g$ is bounded and measurable, and $\epsilon>0$ is given, show there is a measurable simple function $f$ so that $\sup _{x}|g(x)-f(x)| \leq \epsilon$. Is this true if $g$ is not bounded?
2. Suppose $E$ is measurable set of real numbers and let $f(t)=m(E \cap(t-1, t+1))$. Show that $f$ is continuous.
3. Suppose $E$ is a closed set in the upper half-plane whose vertical projection onto the real line is surjective (onto). For each real number $x$ let $y(x)$ be the closest point of $E \cap L_{x}$ to $x$ (here $L_{x}$ is the vertical line through $x$ ). Show that $y$ is a measureable function, but need not be continuous.
4. Given a real number $x \in[0,1]$ let $x_{n}(x) \in\{0,1\}$ be its $n$-binary digit (if this is not unique, choose the epansion ending in all 0's). Let $f(x)=\lim _{\sup _{n \rightarrow \infty}} \frac{1}{n} \sum_{k=1}^{n} x_{n}(x)$. Show that $f$ is measureable. Where is $f$ continuous? Can you guess what $\int_{0}^{1} f(x) d x$ is?
