PSEUDOCONVEXITY FOR THE SPECIAL LAGRANGIAN POTENTIAL EQUATION

F. REESE HARVEY AND H. BLAINE LAWSON, JR.

ABSTRACT. The Special Lagrangian Potential Equation for a function u on a domain $\Omega \subset \mathbb{R}^n$ is given by $\mathrm{tr}\{\arctan(D^2 u)\} = \theta$ for a contant $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$. For C^2 solutions the graph of Du in $\Omega \times \mathbb{R}^n$ is a special Lagrangian submanfold. Much has been understood about the Dirichlet problem for this equation, but the existence result relies on explicitly computing the associated boundary conditions (or, otherwise said, computing the pseudo-convexity for the associated potential theory). This is done in this paper, and the answer is interesting. The result carries over to many related equations – for example, those obtained by taking $\sum_k \arctan \lambda_k^{\mathfrak{g}} = \theta$ where $\mathfrak{g} : \mathrm{Sym}^2(\mathbb{R}^n) \to \mathbb{R}$ is a Gårding-Dirichlet polynomial which is hyperbolic with respect to the identity. A particular example of this is the deformed Hermitian-Yang-Mills equation which appears in mirror symmetry. Another example is $\sum_j \arctan \kappa_j = \theta$ where $\kappa_1, ..., \kappa_n$ are the principal curvatures of the graph of u in $\Omega \times \mathbb{R}$.

We also discuss the inhomogeneous Dirichlet Problem
$$\mathrm{tr}\{\arctan(D_x^2 u)\} = \psi(x)$$
where $\psi : \overline{\Omega} \to (-n\frac{\pi}{2}, n\frac{\pi}{2})$. This equation has the feature that the pullback of ψ to the Lagrangian submanifold $L \equiv \mathrm{graph}(Du)$ is the phase function θ of the tangent spaces of L. On L it satisfies the equation $\nabla \psi = -JH$ where H is the mean curvature vector field of L.

Table of Contents

1. Introduction.

The special Lagrangian potential equation was introduced in [CG] back in 1982. Its solutions u were shown to have the property that the graph $p = \nabla u$ in $\mathbb{R}^n \times \mathbb{R}^n = \mathbb{C}^n$ is a Lagrangian submanifold which is absolutely volume-minimizing, and the linearization at any solution is elliptic. Many examples of these *Special Lagrangian submanifolds* were given in [CG], but the Dirichlet problem for this equation was a difficult challenge. It was first solved in the C^∞-case, for "large phases", in the beautiful paper of Caffarelli, Nirenberg and Spruck [CNS]. Then for all phases, existence and uniqueness of viscosity solutions in the C^0 case were established in [DD].

More specifically, this equation, with **phase** $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$, is written:

$$f(D^2 u) \overset{\text{def}}{=} \text{tr}\left\{\arctan(D^2 u)\right\} = \theta. \tag{1.1}$$

The associated special Lagrangian submanifolds have the property that the n-form $\Phi_\theta \equiv \text{Im}\{e^{-i\theta}dz_1 \wedge \cdots \wedge dz_n\}$ vanishes identically on them, and (with appropriate orientation) they are calibrated by $\text{Re}\{e^{-i\theta}dz_1 \wedge \cdots \wedge dz_n\}$. Now it is an important fact that the set of algebraic solutions, i.e., the constraint set on second derivatives,

$$\mathcal{H}_\theta \equiv \left\{A \in \text{Sym}^2(\mathbb{R}^n) : \Phi_\theta\big|_{\text{graph(A)}} = 0\right\} \tag{1.2}$$

is not connected. Specifically, the equation (1.1) gives rise to the subequation

$$\mathbf{F}_\theta \equiv \{A \in \text{Sym}^2(\mathbb{R}^n) : \text{tr}\left\{\arctan(A)\right\} \geq \theta\}, \tag{1.3}$$

and we have that

$$\mathcal{H}_\theta = \bigcup_{\theta' \equiv \theta \bmod 2\pi} \partial \mathbf{F}_{\theta'} \tag{1.4}$$

where each of the equations $\partial \mathbf{F}_{\theta'}$ is a connected component.

Now the solutions to (1.1) in [CNS] were for phases θ with $(n-1)\frac{\pi}{2} < |\theta| < n\frac{\pi}{2}$. These are the phases where the operator is concave for $\theta > 0$ and convex for $\theta < 0$. In [DD] the solutions are obtained for all phases, i.e., $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$.

The best answer for the existence question for this Dirichlet problem requires computing the asymptotic cone for the subequation $\mathbf{F}_\theta$. For $|\theta| > (n-1)\frac{\pi}{2}$ this was done in [CNS]. The unfinished business, which is completed in this article, is to compute this asymptotic cone for all θ, thereby providing the widest class of domains Ω where existence holds, or, said differently, providing the appropriate notion of boundary pseudo-convexity for the potential theory associated to the SL-operator (1.1). As explained below, the appropriate notion of pseudo-convexity for $\mathbf{F}_\theta$ only depends on $|\theta|$.

Interestingly, as the phases get closer to zero, the restriction on pseudo-convexity gets weaker and weaker. Therefore, for the various phases θ'

appearing in (1.4) above, existence of solutions to the Dirichlet Problem holds on larger and larger categories of domains as $|\theta'| \to 0$.

Specifically, our result is the following Theorem. There is associated to $\mathbf{F}_\theta$ its *asymptotic subequation* $\overrightarrow{\mathbf{F}}_\theta$, which is a cone with vertex at the origin (see Section 3 for the definition). Consider a domain $\Omega \subset \mathbb{R}^n$ with smooth boundary $\partial\Omega$. Let $\mathrm{II}_{x,\partial\Omega}$ denote the second fundamental form of $\partial\Omega$ at x with respect to the interior unit normal $n = n_x$, and let P_n be orthogonal projection onto the line $\mathbb{R}n$. Then we say that $\partial\Omega$ is **strictly $\mathbf{F}_\theta$-convex** at x, if

$$\mathrm{II}_{x,\partial\Omega} + tP_n \ \in \ \mathrm{Int}\,\overrightarrow{\mathbf{F}}_\theta \ \ \text{for } t >> 0,$$

(See also (3.9b) for an equivalent definition.)

In approaching the Dirichlet problem, one needs to consider the subequation $\mathbf{F}_\theta$ **and its dual** $\widetilde{\mathbf{F}}_\theta \equiv\sim \{-\mathrm{Int}\mathbf{F}_\theta\}$. An $\mathbf{F}_\theta$-subharmonic function u is a subsolution, and if $-u$ is an $\widetilde{\mathbf{F}}_\theta$-subharmonic, then u is a supersolution. If both conditions hold, then u is a viscosity solution to the equation (1.1). For the SL protential equation this duality is very pretty. The dual of $\mathbf{F}_\theta$ is

$$\widetilde{\mathbf{F}}_\theta \ = \ \mathbf{F}_{-\theta}.$$

Now this duality carries over to the boundary conditions necessary for existence. At each point the boundary $\partial\Omega$ of the domain must be both strictly $\mathbf{F}_\theta$-convex and strictly $\widetilde{\mathbf{F}}_\theta$-convex. If $\theta' < \theta$, then $\mathbf{F}_{\theta'} \supset \mathbf{F}_\theta$. Hence, we see that the boundary condition for the $\mathbf{F}_\theta$-Dirichlet problem is that $\partial\Omega$ must be strictly $\mathbf{F}_{|\theta|}$-convex at every point. That is, strict $\mathbf{F}_{|\theta|}$ convexity of $\partial\Omega$ is exactly the condition necessary to establish existence for the Dirichlet Problem for the equation $\mathbf{F}_\theta$ for all continuous boundary data. So we want to compute $\overrightarrow{\mathbf{F}}_\theta$ explicitly.

Consider the operator

$$f(A) \equiv \mathrm{tr}\{\arctan(A)\}$$

defined on $\mathbf{F} \equiv \mathrm{Sym}^2(\mathbb{R}^n)$. This operator f has values precisely in the open interval $(-n\frac{\pi}{2}, n\frac{\pi}{2})$. Of these, there are $n - 1$

Special Phases (or Values): $\quad \theta_k \ = \ (n - 2k)\dfrac{\pi}{2}, \quad k = 1, ..., n - 1.$

Removing these $n-1$ special values, the remaining set of values is the disjoint union of n open

Phase Intervals: $\quad I_k \ = \ \left((n - 2k)\dfrac{\pi}{2}, \ (n - 2(k - 1))\dfrac{\pi}{2}\right), \ k = 1, ..., n.$

Let $\lambda_1(A) \leq \lambda_2(A) \leq \cdots$ denote the ordered eigenvalues of A, and let $\sigma_k(A)$ be the kth elementary symmetric function of the eigenvalues of A.

THEOREM 4.1. *The asymptotic subequation* $\overrightarrow{\mathbf{F}}_\theta$ *of* $\mathbf{F}_\theta$, *for* $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$, *is given as follows.*

(1) *If* $\theta \in I_k$ $(k = 1, ..., n)$, *then*
$$\overrightarrow{\mathbf{F}}_\theta \;=\; \mathbf{\Lambda}_k \;\equiv\; \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : \lambda_k(A) \geq 0\}.$$

(2) *If* θ_k $(k = 1, ..., n-1)$ *is a special value, then*
$$\overrightarrow{\mathbf{F}}_{\theta_k} \;=\; \mathbf{\Lambda}_k^{\sigma_{n-1}}.$$

The set $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ depends on the Gårding polynomial $\sigma_{n-1}(A)$ whose eigenvalues *cannot* be computed in terms of the eigenvalues of A. (See the subsection "branches" in section 3.) However, from Proposition 4.5 we have the following.

Proposition 1.1. *For* $k = 1, ..., n-1$, *the set* $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ *is a disjoint union* $\mathbf{\Lambda}_k^{\sigma_{n-1}} = \mathbf{\Lambda}_k \cup E_k$ *where*
$$E_k \;\equiv\; (\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{\sigma_j(A)\,\sigma_n(A) < 0\}$$
and where j *is defined by the condition:* $\sigma_j(A) \neq 0$ *and* $\sigma_\ell(A) = 0$ *for* $j < \ell \leq n - 1$.

An application of this result is to the existence question for the Dirichlet problem. For this one needs to know the interior of $\mathbf{\Lambda}_k^{\sigma_{n-1}}$. Part (2) of the following is not obvious from Proposition 1.1. Note that the terms with $j < n - 1$ do not enter. This is done is Proposition 4.5.

THEOREM 4.6. *The interior of* $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ *is given as follows.*

(1) *If* $\theta \in I_k$ $(k = 1, ..., n)$, *then*
$$\mathrm{Int}\,\overrightarrow{\mathbf{F}}_\theta \;=\; \mathrm{Int}\mathbf{\Lambda}_k \;\equiv\; \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : \lambda_k(A) > 0\}.$$

(2) *If* θ_k $(k = 1, ..., n-1)$ *is a special value, then*
$$\mathrm{Int}\,\overrightarrow{\mathbf{F}}_{\theta_k} \;=\; \{\mathrm{Int}\mathbf{\Lambda}_{k+1} \cap \mathbf{\Lambda}_k\} \cup E_k^\star$$
where
$$E_k^\star \;\equiv\; (\mathrm{Int}\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{\sigma_{n-1}(A)\,\sigma_n(A) < 0\}$$

Using Theorem 4.6 we give a deeper version of our general results on the Dirichlet problem [DD] for this equation. Note that as k increases from 1 to $[n/2]$, the sets $\mathbf{\Lambda}_k$ get quite large. The first $k - 1$ eigenvalues of A can be arbitrarily negative. So for the intervals close to the origin the geometric constraints on the second fundamental form of the boundary of the domain are quite loose. This general existence and uniqueness result for the SL Dirichlet problem is given in Section 5.

There has also been work on the inhomogeneous Dirichlet problem

$$\text{tr}\left\{\arctan(D^2u)\right\} \;=\; \psi(x) \tag{1.5}$$

where ψ is a continuous function on the closed domain with values in a high phase interval. Solutions in the C^∞ category were obtained by Tristan Collins, Sebastien Picard and Xuan Wu [CPW] where the interval is the critical one: $((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$. (See Theorem 6.3.) The analogue of this result in the continuous case was done by S. Dinew, H.-S. Do and T. D. Tô in [DDT]. Recently, Marco Cirant and Kevin Payne have established comparison for this equation when ψ does not take on a special value, in other words, when ψ takes its values in (any) one of the phase intervals I_k (see [CP, §6.4] and Theorem 6.2 below).

In fact using [CP, §6.4] and Theorem 2.1 we get the following. Let $\Omega \subset\subset \mathbb{R}^n$ be a domain with smooth boundary, and at each $x \in \Omega$ let $\kappa_1(x) \leq \cdots \leq \kappa_{n-1}(x)$ be the ordered principal curvatures of $\partial\Omega$, i.e., the eigenvalues of the second fundamental form w.r.t. the inner normal. Then $\partial\Omega$ is said to be **strictly k-convex** if $\kappa_k(x) > 0$ for all $x \in \partial\Omega$. For the following we will need the boundary $\partial\Omega$ to be both strictly k-convex and strictly $(n-k+1)$-convex by the duality in the arguments. Of course this condition for the lesser principal curvature is enough.

THEOREM 6.2. Part C. *Suppose that $\partial\Omega$ is strictly $\min\{k, n-k+1\}$-convex. Let $\psi \in C(\overline{\Omega})$ be an inhomogeneous term with values in I_k, i.e.,*

$$\psi(\overline{\Omega}) \;\subset\; I_k \;=\; \left((n-2k)\frac{\pi}{2}, (n-2(k-1))\frac{\pi}{2}\right).$$

Then existence and uniqueness hold for the Dirichlet problem for any continuous boundary values $\varphi \in C(\partial\Omega)$.

This is the best result so far for the inhomogeneous Dirichlet problem in the continuous setting.

It is an interesting question whether Theorem 6.2 could be extended to general functions $\psi : \overline{\Omega} \to (-n\frac{\pi}{2}, n\frac{\pi}{2})$.

We would like to point out that solutions to (1.5) have a very nice geometric interpretation which goes back to [CG]. If u is a smooth function on a domain $\Omega \subset \mathbb{R}^n$, then the graph of Du on $\Omega \times \mathbb{R}^n$ is a Lagrangian submanifold L of $\mathbb{R}^n \times \mathbb{R}^n$. This gives us a **phase function** $\theta : L \to \mathbb{R}/2\pi\mathbb{Z}$ for the tangent planes of L by setting $\text{Re}\{dz_1 \wedge \cdots \wedge dz_n\} = e^{i\theta}$. Furthermore, as pointed out in [CG], this phase function satisfies the equation

$$\nabla\theta = -JH \qquad \text{on} \;\; L \tag{1.6}$$

where H is the mean curvature vector of L. This proves that a Lagrangian submanifold is minimal if and only if it has constant phase (and is therefore special Lagrangian). The equation (1.6) was left as an exercise in [CG].

However, since this paper is devoted to the SL potential equation, we have inserted a proof in Appendix A.

Now note that if u is a smooth solution to (1.5), then the phase function θ is just the pull-back of ψ to $L = \mathrm{graph}(Du)$. In particular, that pull-back satisfies (1.6).

The result in [CPW], discussed above, led us to show that the special Lagrangian potential operator satisfies the condition, in our paper [IDP], of being "tamable". In Theorem 6.1 we prove that $\tan\left\{\frac{1}{n}f(A)\right\}$ is tame on $\mathbf{F}_\theta =$ the inverse image under f of any subinterval $[(n-2)\frac{\pi}{2} + \delta, n\frac{\pi}{2})$ of the top phase interval I_1. Here $\theta \equiv (n-2)\frac{\pi}{2} + \delta$ and $\delta > 0$. As a result we get a different proof of the result of [DDT] mentioned above and stated in Theorem 6.2.

With this same phase constraint, Ryosuke Takahashi [T, Thm. 1.1], also applying the tangent function to $f(A)$, proved that the composition $\tan f(A)$ is concave on $\mathbf{F}_\theta$ if $\theta > (n-2)\frac{\pi}{2}$. This important result allows Takahashi to apply Evans-Krylov with many consequences.

The SL subequation $\mathbf{F}_\theta \equiv \{f(A) \equiv \sum_i \arctan \lambda_i(A) \geq \theta\}$, which is defined in terms of the eigenvalues of A, is **universal** in the sense that it defines many associated subequations as we now explain.

Definition 1.2. Let $\mathfrak{g} : \mathrm{Sym}^2(\mathbb{R}^n) \to \mathbb{R}$ be a homogeneous polynomial of degree m which is Gårding hyperbolic with respect to the identity I. This means that $\mathfrak{g}(tI + A)$ is a polynomial having all real roots for every $A \in \mathrm{Sym}^2(\mathbb{R}^n)$. The negatives of the roots are called the **Gårding eigenvalues**, which we list in order

$$\lambda_1^{\mathfrak{g}}(A) \leq \cdots \leq \lambda_m^{\mathfrak{g}}(A), \tag{1.7}$$

so $\mathfrak{g}(tI + A) = \mathfrak{g}(I) \prod_{k=1}^m (t + \lambda_k^{\mathfrak{g}}(A))$. The open set Γ where $\lambda_1^{\mathfrak{g}}(A) > 0$ (i.e., where all the Gårding eigenvalues are > 0), is a convex cone containing I, and is called the **Gårding cone**. It has the property that for each k

$$\lambda_k^{\mathfrak{g}}(A) < \lambda_k^{\mathfrak{g}}(A + B) \qquad \text{for all } B \in \Gamma. \tag{1.8}$$

([HP, Thm. 2.1] or [HP2]). In particular, the **Gårding branches**

$$\mathbf{\Lambda}_k^{\mathfrak{g}} = \{A : \lambda_k^{\mathfrak{g}}(A) \geq 0\} \tag{1.9}$$

satisfy $\mathbf{\Lambda}_k^{\mathfrak{g}} + \overline{\Gamma} \subset \mathbf{\Lambda}_k^{\mathfrak{g}}$ for all k. If, in addition, $\mathcal{P} \equiv \{A \geq 0\} \subset \overline{\Gamma}$,we call $\mathfrak{g}$ a **Gårding-Dirichlet** polynomial. In this case each of the Gårding branches is a subequation (see the beginning of the next section).

Definition 1.3. Given a Gårding-Dirichlet polynomial $\mathfrak{g}$ we define the $\mathfrak{g}$-**special Lagrangian potential operator** (or $\mathfrak{g}$-**SL operator** for short)

$$f^{\mathfrak{g}}(A) \equiv \sum_{k=1}^m \arctan(\lambda_k^{\mathfrak{g}}(A)) \tag{1.10}$$

for $A \in \mathrm{Sym}^2(\mathbb{R}^n)$ with values in $(-m\frac{\pi}{2}, m\frac{\pi}{2})$. We define the subequation

$$\mathbf{F}_\theta^{\mathfrak{g}} \equiv \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : f^{\mathfrak{g}}(A) \geq \theta\} \quad \text{for each } \theta \in \left(-m\frac{\pi}{2}, m\frac{\pi}{2}\right), \quad (1.11)$$

and the associated **$\mathfrak{g}$-special Lagrangian potential equation**

$$\partial \mathbf{F}_\theta^{\mathfrak{g}} \equiv \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : f^{\mathfrak{g}}(A) = \theta\}. \qquad (1.12)$$

That $\mathbf{F}_\theta^{\mathfrak{g}}$ is a subequation follows from (1.8) and the assumption $\mathcal{P} \subset \Gamma$.

The special phases and the phase intervals are defined exactly as above with n replaced by m. The existence and uniqueness go through for these equations exactly as in the basic case. (See Section 3.) Our boundary calculation also holds.

GENERALIZED THEOREM 4.1. *Let $\mathfrak{g}$ be a Gårding-Dirichlet polynomial as above. Then the asymptotic subequation $\overrightarrow{\mathbf{F}}_\theta^{\mathfrak{g}}$ of $\mathbf{F}_\theta^{\mathfrak{g}}$, for $\theta \in (-m\frac{\pi}{2}, m\frac{\pi}{2})$, is given as follows.*

(1) *If $\theta \in I_k$ $(k = 1, ..., m)$, then*

$$\overrightarrow{\mathbf{F}}_\theta^{\mathfrak{g}} = \mathbf{\Lambda}_k^{\mathfrak{g}}.$$

(2) *If θ_k $(k = 1, ..., m-1)$ is a special value, then*

$$\overrightarrow{\mathbf{F}}_{\theta_k}^{\mathfrak{g}} = \mathbf{\Lambda}_k^{\sigma_{m-1}^{\mathfrak{g}}}.$$

This result along with the analogue of Theorem 4.6 (Proposition 7.3), will be proved in Section 7. However, the proofs are parallel to the basic case, and the reader should first study those arguments.

Examples. On $\mathbb{C}^n$ we can take $\mathfrak{g}$ to be the determinant of the complex symmetric part $\frac{1}{2}(A - JAJ)$ of A, and we get the complex version of the special Lagrangian potential equation, which is related to mirror symmetry, as noted below. There is a similar quaternionic case with $\mathfrak{g}$ equal to $\frac{1}{4}(A - IAI - JAJ - KAK)$. In fact this process yields an infinite array of equations, and is discussed in more detail in Section 7.

Another interesting incarnation of the SL potential equation is the following. Let $u : \Omega \to \mathbb{R}$ be a smooth function on a domain $\Omega \subset \mathbb{R}^n$, and let $\Gamma \subset \Omega \times \mathbb{R}$ be its graph. For each $x \in \Omega$, let $\kappa_1(x), ..., \kappa_n(x)$ be the eigenvalues of the second fundamental form, i.e., the *principle curvatures*, of Γ above x. Then we can consider the subequation $\mathcal{F}_{\theta,\rho}$ given by $\sum_{k=1}^n \arctan(\rho \kappa_k) \geq \theta$ for $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$ and $\rho > 0$. This equation was first studied by Graham Smith in [GS1]. He considered the case where $\theta \in [(n-1)\frac{\pi}{2}, n\frac{\pi}{2})$ where all the principal curvatures must be positive. The special case where $\theta = (n-1)\frac{\pi}{2}$ has a very nice geometric interpretation. Actually, Smith considered this for hypersurfaces in a general riemannian manifold. The paper [GS1] principally concerned rigidity and pre-compactness theorems. However, in [GS2] he considered the Dirichlet problem, for the same equations,

on domains in Hadamard manifolds. He went on to establish "parametric" versions of these theorems for general convex curvature functions (see, for example, [GS3], [CS], [GS4]).

Concerning the standard Dirichlet problem for this equation, even though it is constant coefficient (but not pure second order), comparison is an open question (although a weak form of comparison does hold). Nevertheless, existence was established in [DDR], for all θ, on any domain in $\mathbb{R}^n$ whose boundary satisfies the appropriate $\mathcal{F}_\theta$ convexity. Furthermore, a version of our Theorem 3.1, explicitly computing this convexity condition, holds for this equation. This is discussed in the last subsection of Section 6.

Using the results in [DDR] these results carry over to riemannian manifolds with a topological G-structure. This is discussed in Section 8.

Some Further Historical Notes. There is now a vast literature on the SL potential equation. The papers touch on many different topics, and we thought it might be interesting to mention some examples. However, this is certainly not a complete history.

In Lemma 2.1 of [Y2], Yu Yuan proves that

$$\partial \mathbf{F}_\theta \ \text{ is convex (for some orientation)} \qquad \Longleftrightarrow \qquad |\theta| \geq (n-2)\frac{\pi}{2}.$$

For this reason $((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$ is called the **critical phase interval**.

Dake Wang and Yu Yuan [WY1] showed that, for $m = 2, 3, ...,$ there exist (viscosity) solutions u_m to the SL Potential Equation which are $C^{1,\frac{1}{2m-1}}$ but not $C^{1,\delta}$ for $\delta > \frac{1}{2m-1}$. In fact these solutions are analytic outside the origin. Graphing their gradients gives special Lagrangian submanifolds with a isolated singularity at the origin.

Recently, J. Chen, R. Shankar and Y. Yuan proved that convex viscosity solutions to the special Lagrangian potential equation are real analytic [CSY].

In another version of the boundary value problem, Simon Brendle and Micah Warren [BW] proved that if $\Omega_1, \Omega_2 \subset\subset \mathbb{R}^n$ have smooth, strictly convex boundaries (second fundamental forms > 0), then there is a diffeomorphism $\Phi : \overline{\Omega_1} \to \overline{\Omega_2}$ whose graph is special Lagrangian (for some phase θ).

There is a large literature concerning the SL potential equation and mean curvature flow. A good survey is given by Wang [W].

People have worked on showing existence of Special Lagrangian submanifolds by minimizing volume among just among Lagrangians. (Recall from [CG] that Lagrangian **and** minimal implies special Lagrangian; see (1.6) and Appendix A.) This was started by the work of Schoen and Wolfson [SW1,2].

It turns out to be quite subtle. Wolfson [Wo] found an example of a minimizer among Lagrangians that was not minimal. This lead to looking at mean curvature flow. Here singularities occur quite often in finite time (cf. A. Neves [N1,3]). See the surveys [N2] and [W].

There is a Bernstein-type theorem proved for $n = 2$ by Lei Fu [F] and for general n by Y. Yuan [Y1] and also by Jost and Xin [JX]. It says that if $u : \mathbb{R}^n \to \mathbb{R}$ is a global solution of the SL potential equation with phase $|\theta| \in ((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$ (the critical phase interval), then u is quadratic.

A degenerate form of the SL potential equation governs geodesics in the space of positive graph Lagrangians in $\mathbb{C}^n$. The program for studying this space was initiated by Jake Solomon, and he and Yanir Rubinstein [RS] were able to solve this geodesic equation with a continuous solution in the sense of [DD]. Matt Dellatorre expanded these results to manifolds with curvature ≤ 0 [De]. It is very interesting that this program is much like the program which lead to the solution of the Donaldson-Tian-Yau conjecture [CDS]. Recently Collins and Yau [CY] have studied geodesics on an infinite dimensional space which is mirror to Solomon's. This is aimed at understanding the deformed Hermitian-Yang-Mills equation which is "mirror" to the SL potential equation.

There is a fundamental article by N. Hitchin [H] on the moduli space of special Lagrangians, and many important articles by D. Joyce. Some more recent articles are [Jo1], [Jo2] and [JLS]. Joyce's earlier work is surveyed in [Jo3] (together with a large overview of the field). There is also a moment map point of view on this equation given by Donaldson [D].

The SL potential equation plays a big role in mirror symmetry. This began with the paper of A. Strominger, S.-T. Yau and E. Zaslow [SYZ] which gave a very geometric picture of how mirror manifolds are connected. Special Lagrangians and the SL potential equation are critical in this tableau. See, for example, the very good articles [LYZ], [JY], [J], [CJY], [CXY], [CSh]. The reader should consult these sources, but a small insight comes from the following. Let (X, ω) be an n-dimensional Kähler manifold and $a \in H^{1,1}(X, \mathbb{R})$ a fixed (1,1)-homology class. One is interested in finding an element $\alpha \in a$ such that

$$\mathrm{Im}\left(e^{-i\theta}(\omega + i\alpha)^n\right) = 0.$$

The angle θ is determined topologically by

$$\theta = \arg\left\{\int_X (\omega + i\alpha)^n\right\}.$$

This gives rise to a hermitian Yang-Mills equation

$$\Theta_\omega(\alpha) = \sum_k \arctan(\lambda_k) \equiv \theta \pmod{2\pi}$$

where the λ_k's are eigenvalues of an endomorphism $K : T^{1,0}X \to T^{1,0}X$ given by contracting by α and the dual of ω. Of course the elements in a all differ from a given one α_0 by $dd^c u$ for a function u on X.

We point out that the work of R. Takahashi, referred to above, has consequences for some of these mirror symmetry results (see [T] for details).

Very recently Gao Chen confirmed a mirror version of the Thomas-Yau conjecture (see [GC1-2]).

We want to thank the referee for his/her useful remarks, and particularly for noticing an oversight in Proposition 4.5.

2. Geometric Conditions for Strict $\overrightarrow{\mathbf{F}}_\theta$-Boundary Convexity

The best boundary condition for existence in the $\mathbf{F}_\theta$-Dirichlet problem is the strict $\overrightarrow{\mathbf{F}}_{|\theta|}$-convexity of $\partial\Omega$ at each point. As explained above, one needs in general to verify convexity for both the subequation and its dual. However, the dual of $\mathbf{F}_\theta$ is $\mathbf{F}_{-\theta}$, and $\mathbf{F}_\theta \subset \mathbf{F}_{-\theta}$ if $\theta \geq 0$, so that one only need verify boundary convexity for the smaller $\mathbf{F}_\theta$.

The condition of strict $\overrightarrow{\mathbf{F}}_\theta$-convexity can be computed entirely in terms of the geometry of $\partial\Omega$. Although we only need $\theta \geq 0$, we give the result for all θ.

THEOREM 2.1. *Fix $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$. Let $x \in \partial\Omega$ and let*

$$\kappa_1 \leq \cdots \leq \kappa_{n-1}$$

be the principle curvatures of the second fundamental form at x w.r.t. the interior unit normal n. Then $\partial\Omega$ is strictly $\overrightarrow{\mathbf{F}}_\theta$-convex at x if and only if:

   (1)   *for $\theta \in I_k$ (the kth phase interval) where $k < n - 1$, one has*

$$\kappa_k > 0,$$

   (2)   *for $\theta = \theta_k = (n - 2k)\frac{\pi}{2}$, a special phase with $1 \leq k \leq n - 2$, either*

      (a)   *$\kappa_{k+1} > 0$ and $\kappa_k \geq 0$, or*

      (b)   *$\kappa_{k+1} > 0$, $\kappa_k < 0$, and $\sigma_{n-1}(\kappa)\sigma_{n-2}(\kappa) < 0$*

where $\sigma_\ell(\kappa)$ denotes the ℓth elementary symmetric function of the κ_i's.

   (3) *for $\theta = \theta_{n-1}$ or for $\theta \in I_n$, there is no condition. (Every boundary is strictly $\overrightarrow{\mathbf{F}}_\theta$-convex.)*

Thus for the smallest phases $-n\frac{\pi}{2} < \theta \leq (-n + 2)\frac{\pi}{2}$, where $\overrightarrow{\mathbf{F}}_\theta$ is large, there is no condition. However, as θ increases, the subequation $\overrightarrow{\mathbf{F}}_\theta$ decreases, culminating in the most stringent case $\overrightarrow{\mathbf{F}}_\theta = \mathcal{P}$ when $\theta \in I_1$.

Proof. Consider the diagonal matrix

$$A = \begin{pmatrix} \kappa_1 & & & & & \\ & \kappa_2 & & & & \\ & & \kappa_3 & & & \\ & & & \ddots & & \\ & & & & \kappa_{n-1} & \\ & & & & & t \end{pmatrix}.$$

written with respect to an orthonormal basis of principal directions in $T_x(\partial\Omega)$ and n. The condition is that A should lie in Int $\overrightarrow{\mathbf{F}}_\theta$ for all $t >> 0$ (cf. Cor. 5.4 in [DD]). We use Theorem 4.6. If $\theta \in I_k$ for $k \leq n - 1$, we have $\kappa_k > 0$. This proves (1). If $\theta \in I_n$, then we only need $t > 0$ which is always true. If

$\theta = \theta_k$, then either (a) or (b) must hold, for $k < n-1$. When $k = n-1$, the nth eigenvalue is t, which is $>> 0$, and the $(n-1)^{\text{st}}$ eigenvalue κ_{n-1} is either ≥ 0 or < 0. In this second case all κ_i's are < 0 and $\sigma_{n-1}(A)\sigma_n(A) < 0$ for all t large (see (2.1) below.) ∎

Definition 2.2. If the kth ordered principal curvature at $x \in \partial\Omega$ satisfies $\kappa_k > 0$ we say that $\partial\Omega$ is strictly k-**convex** at x. This means that $\partial\Omega$ has at least $n-k$ strictly positive principle curvatures at x. Notice in particular that strictly 1-convex means the hypersurface $\partial\Omega$ is strictly convex near x in the usual sense.

Examples of Strictly ℓ-Convex Boundaries. Let $M \subset \mathbb{R}^n$ be a smooth compact submanifold of dimension $\ell - 1$ (codimension $k+1$ with $k = n-\ell$). For $\epsilon > 0$ let

$$S_\epsilon(M) \equiv \{x : \text{dist}(x, M) = \epsilon\}.$$

For ϵ sufficiently small, $S_\epsilon(M)$ is regular and diffeomorphic to the normal sphere bundle of M. It bounds the domain $\Omega_\epsilon(M) = \{x : \text{dist}(x, M) \leq \epsilon\}$. For $\epsilon > 0$ even smaller $S_\epsilon(M) = \partial\Omega_\epsilon(M)$ has the property that at each point the second fundamental form has at least k strictly positive eigenvalues (coming from the normal spheres). That is, the hypersurface $S_\epsilon(M)$ is strictly $(n-k) = \ell$ convex. Thus there are many many strictly $\mathbf{\Lambda}_\ell$-convex boundaries in $\mathbb{R}^n$, and in fact in any n-manifold. Here is a picture of a strictly 2-convex surface in $\mathbb{R}^3$.

We now consider the case of a special phase $\theta = \theta_k$, $1 \leq k \leq n-1$. At a point where (2)(a) holds, we have that $\partial\Omega$ is k-convex and also $\kappa_{k+1} > 0$.

If (2)(b) holds, i.e., if $\kappa_{k+1} > 0$, $\kappa_k < 0$, and $\sigma_n(\kappa)\sigma_{n-1}(\kappa) < 0$, we have

$$\frac{\sigma_{n-1}(A)}{\sigma_n(A)} = \frac{1}{t} + \frac{1}{\kappa_{n-1}} + \frac{1}{\kappa_{n-2}} + \cdots + \frac{1}{\kappa_1}. \tag{2.1}$$

Now this is < 0 for all large t iff

$$\frac{\sigma_{n-2}(\text{II})}{\sigma_{n-1}(\text{II})} = \frac{1}{\kappa_{n-1}} + \frac{1}{\kappa_{n-2}} + \cdots + \frac{1}{\kappa_1} < 0. \tag{2.2}$$

where

$$
\mathrm{II} \;=\; \begin{pmatrix} \kappa_1 & & & & \\ & \kappa_2 & & & \\ & & \kappa_3 & & \\ & & & \ddots & \\ & & & & \kappa_{n-1} \end{pmatrix}.
$$

is the second fundamental form of $\partial\Omega$.

Examples for the Special Phases.

Example 2.3. $(k = 1, n = 3)$. When is an oriented surface $\Sigma \subset \mathbb{R}^3$ strictly $\mathbf{\Lambda}_1^{\sigma_2}$-convex? This happens exactly when either:

(1) The second fundamental form of Σ is ≥ 0, and so the Gauss curvature $K = \kappa_1\kappa_2 \geq 0$, and the mean curvature $H = \kappa_1 + \kappa_2 > 0$.

(2) Otherwise we have $K < 0$ and $H > 0$.

This last fact follows from (2.2) which says

$$
\frac{\sigma_1(\mathrm{II})}{\sigma_2(\mathrm{II})} \;=\; \frac{H}{K} \;<\; 0.
$$

Example 2.4. $(k = 1$ but general $n)$ The hypersurface $\partial\Omega$ is strictly $\mathbf{\Lambda}_1^{\sigma_{n-1}}$-convex when either:

(1)   The second fundamental form of $\partial\Omega$ is ≥ 0, and so the Gauss-Kronecker curvature $K_{GK} \overset{\text{def}}{=} \det(\mathrm{II}) = \sigma_{n-1}(\mathrm{II}) \geq 0$, and $\kappa_2 > 0$.

(2)   Otherwise we have $K_{GK} < 0$ and $\sigma_{n-2}(\mathrm{II}) > 0$.

Example 2.5. $(k = 2, n = 4)$. When is a hypersurface $\partial\Omega \subset \mathbb{R}^4$ strictly $\mathbf{\Lambda}_2^{\sigma_3}$-convex? The boundary $\partial\Omega$ has principle curvatures $\kappa_1 \leq \kappa_2 \leq \kappa_3$. Then $\kappa_3 > 0$ and either $\kappa_2 \geq 0$ or $\kappa_2 < 0$. In this second case

$$
\frac{\sigma_2(\mathrm{II})}{\sigma_3(\mathrm{II})} \;=\; \frac{1}{\kappa_1} + \frac{1}{\kappa_2} + \frac{1}{\kappa_3} \;<\; 0.
$$

Here the Gauss-Kronecker curvature $\sigma_3(\mathrm{II}) > 0$, and $\sigma_2(\mathrm{II}) < 0$.

As mentioned above, for the $\mathbf{F}_\theta$ Dirichlet Problem we need the boundary to be strictly $\overrightarrow{\mathbf{F}}_{|\theta|}$-convex at each point. Here there is a difference between n even and n odd.

Suppose $n = 2m$**.** Then we have

$$
I_k \;=\; ((m - k)\pi, (m - k + 1)\pi)
$$

and the non-negative special values are $(m - k)\pi$ for $1 \leq k \leq m$. Note in particular that 0 is a special value.

Suppose $n = 2m + 1$**.** Then we have
$$I_k \;=\; ((m - k + \tfrac{1}{2})\pi, (m - k + \tfrac{3}{2})\pi)$$
and the non-negative special values are $(m - k)\pi$ for $1 \le k \le m$.

Remark 2.5. **(Caffarelli - Nirenberg - Spruck).** In the ground-breaking paper [CNS] the authors considered the case where
$$\theta \;\equiv\; 0 \,(\mathrm{mod}\ \pi)$$
and solved the Dirichlet problem for θ in the uppermost interval. For n odd, the boundary condition was strict convexity ($\kappa_1 > 0$). However, for n even, this θ is the largest special value. From Theorem 4.1 part (2) the strict boundary convexity condition is either $\kappa_2 > 0$ and $\kappa_1 \ge 0$ or $\kappa_2 > 0$, $\kappa_1 < 0$ and $\sigma_{n-1}\sigma_{n-2} < 0$. In the second case $\sigma_{n-1} < 0$ and so $\sigma_{n-2} > 0$. In the first case we also have $\sigma_{n-2} > 0$ because $\kappa_2 > 0$. Thus the strict convexity condition is exactly
$$\sigma_{n-2}(\kappa_1, ..., \kappa_{n-1}) \;>\; 0.$$

For a connected boundary $\partial\Omega$ of a compact domain, [CNS] had an elegant argument. There is always a point $x \in \partial\Omega$ where the second fundamental form II is > 0. Therefore II maps into the highest connected component of $\{\sigma_{n-2} \neq 0\}$ (the one containing the identity). Since $\sigma_{n-2} = 0$ on the boundary of this region b cannot touch that boundary by the strictness assumption.

Remark 2.6. Perhaps it is worth noting that the proof of Theorem 2.1 can be interpreted as computing the restriction of the subequation $\overrightarrow{\mathbf{F}}_\theta$ to the hyperplane $T_x\partial\Omega$. From this perspective, the condition in Theorem 2.1 imposed on the second fundamental form $\mathrm{II}_{x,\partial\Omega}$ is that $\mathrm{II}_{x,\partial\Omega}$ must belong to the $\mathrm{Int}\left(\overrightarrow{\mathbf{F}}_\theta\big|_{T_x\partial\Omega}\right)$ of the restricted subequation $\overrightarrow{\mathbf{F}}_\theta\big|_{T_x\partial\Omega} \subset \mathrm{Sym}^2(T_x\partial\Omega)$ on $T_x\partial\Omega$ (see [Rest]). So, for example, in part (1) where $\overrightarrow{\mathbf{F}}_\theta = \mathbf{\Lambda}_k$, we have computed that $\mathbf{\Lambda}_k\big|_{T_x\partial\Omega} = \mathbf{\Lambda}_k(T_k\partial\Omega)$, the kth branch of det $= 0$ on $T_x\partial\Omega$, and the requirement is that $\mathrm{II}_{x,\partial\Omega} \in \mathrm{Int}\mathbf{\Lambda}_k(T_x\partial\Omega)$.

3. Preliminaries

For the purposes of this paper a **subequation** is a closed subset $\mathbf{F} \subset \mathrm{Sym}^2(\mathbb{R}^n)$ which is $\mathcal{P}$-monotone, i.e.,

$$\mathbf{F} + \mathcal{P} \ \subset \ \mathbf{F}$$

where $\mathcal{P} \equiv \{A \geq 0\}$. Associated to a subequation $\mathbf{F}$ there is a generalized potential theory, which starts with the following concept. Given a domain $\Omega \subset \mathbb{R}^n$ let $\mathrm{USC}(\Omega)$ be the set of functions $u : \Omega \to [-\infty, \infty)$ which are upper semi-continuous. Then a function $u \in \mathrm{USC}(\Omega)$ is **F-subharmonic** if for each $x \in \Omega$ and each C^2-function $\phi \geq u$ in a neighborhood of x with $\phi(x) = u(x)$, we have $D_x^2\phi \in \mathbf{F}$.

The Special Lagrangian Potential Equation

The subequations of concern in this paper are defined as follows.

Definition 3.1. The **Special Lagrangian Potential Operator**, defined by

$$f(A) \ \equiv \ \mathrm{tr}\left\{\arctan A\right\}, \qquad \text{for} \ \ A \in \mathrm{Sym}^2(\mathbb{R}^n), \tag{3.1a}$$

takes values in the interval $(-n\frac{\pi}{2}, n\frac{\pi}{2})$. Given a phase $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$, let

$$\mathbf{F}_\theta \ \equiv \ \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : f(A) \geq \theta\} \tag{3.1b}$$

denote the **SL-potential subequation of phase** θ. The associated equation

$$\partial\mathbf{F}_\theta \ \equiv \ \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : f(A) = \theta\} \tag{3.1c}$$

is called the **SL-potential equation of phase** θ, and is usually written as

$$\mathrm{tr}\{\arctan D^2 u\} \;=\; \theta. \tag{3.1d}$$

The Asymptotic Interior

There are two canonical subequations associated to each subequation $\mathbf{F}$: the **monotonicity subequation** $\mathbf{M_F} \equiv \{A : \mathbf{F} + A \subset \mathbf{F}\}$, and the **asymptotic subequation** $\overrightarrow{\mathbf{F}}$, which determines the appropriate strict boundary convexity condition for existence in the Dirichlet problem. One of the main points of this paper is to compute $\overrightarrow{\mathbf{F}}_\theta$ for the SL subequation $\mathbf{F}_\theta$.

There are two approaches to defining and computing the asymptotic subequation $\overrightarrow{\mathbf{F}}$ for a general subequation $F \subset \mathrm{Sym}^2(\mathbb{R}^n)$. Both approaches are enhancements of ideas from [CNS]. For the first approach we refer the reader to [DD, Sec. 5] where a rather complete description of various cones which lead to $\overrightarrow{\mathbf{F}}$ is given, along with examples showing the necessity of the indirect approach using these auxiliary cones. (In [DD] $\overrightarrow{\mathbf{F}}$ is called the *asymptotic ray set* of F.)

Actually it is better to define and compute the interior of $\overrightarrow{\mathbf{F}}$ since it is really this which determines the strict boundary convexity.

This second approach was given in [DDR]. It has two advantages. First it is direct and does not require the auxiliary cones. Secondly, it defines the interior of $\overrightarrow{\mathbf{F}}$, which we provisionally denote by $\overrightarrow{\mathrm{Int}\,\mathbf{F}}$. Then $\overrightarrow{\mathbf{F}}$ is defined to be its closure. This is the approach taken here.

Definition 3.2. Given a subequation $\mathbf{F}$ the **asymptotic interior of $\mathbf{F}$** is defined to be

$$\overrightarrow{\mathrm{Int}\,\mathbf{F}} \;\equiv\; \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : \; \exists\, \epsilon > 0 \text{ and } t_0 \text{ s.t. } t(A - \epsilon I) \in \mathbf{F} \;\forall\, t \geq t_0\}.$$

The closure $\overrightarrow{\mathbf{F}}$ of $\overrightarrow{\mathrm{Int}\,\mathbf{F}}$ is called the **asymptotic subequation** for $\mathbf{F}$.

Proposition 3.3. *Let $\mathbf{F}$ be a subequation which is $\neq \emptyset$ and not equal to $\mathrm{Sym}^2(\mathbb{R}^n)$. Then $\overrightarrow{\mathrm{Int}\,\mathbf{F}}$ is an open cone with vertex at the origin, and it is $\mathcal{P}$-monotone. Its closure is a subequation $\overrightarrow{\mathbf{F}}$ also $\neq \emptyset$ or $\mathrm{Sym}^2(\mathbb{R}^n)$. Finally, the interior of $\overrightarrow{\mathbf{F}}$ is equal to the provisional set $\overrightarrow{\mathrm{Int}\,\mathbf{F}}$ (i.e., $\mathrm{Int}\,\overrightarrow{\mathbf{F}} = \overrightarrow{\mathrm{Int}\,\mathbf{F}}$).*

Proof. It is easy to see from its definition that $\overrightarrow{\mathrm{Int}\,\mathbf{F}}$ is a cone with vertex at the origin and that it is $\mathcal{P}$-monotone. Let

$$\mathcal{N}_\epsilon(A) \;\equiv\; A - \epsilon I + \mathrm{Int}\mathcal{P} \tag{3.2}$$

denote the "ϵ-neighborhood of A". Then the definition of $\overrightarrow{\text{Int}}\,\mathbf{F}$ can be reformulated as

$$\overrightarrow{\text{Int}}\,\mathbf{F} \;=\; \{A : \exists\, \epsilon > 0 \text{ and } t_0 \text{ s.t. } t\mathcal{N}_\epsilon(A) \subset \mathbf{F} \;\forall\, t \geq t_0\}. \qquad (3.3)$$

Now if $A \in \overrightarrow{\text{Int}}\,\mathbf{F}$, that is, $t\mathcal{N}_\epsilon \subset F$ for all $t \geq t_0$, then $\forall\, B \in \mathcal{N}_{\frac{\epsilon}{2}}(A)$, we have $t\mathcal{N}_{\frac{\epsilon}{2}}(B) \subset t\mathcal{N}_\epsilon(A) \subset F$ for all $t \geq t_0$, which proves that $\overrightarrow{\text{Int}}\,\mathbf{F}$ is open. If $-I \in \overrightarrow{\text{Int}}\,\mathbf{F}$, then from (3.3) we see that $\mathbf{F} = \text{Sym}^2(\mathbb{R}^n)$ contrary to assumption.

Since $\Gamma \equiv \overrightarrow{\text{Int}}\,\mathbf{F}$ is an open $\mathcal{P}$-monotone set which is non-empty and not equal to $\text{Sym}^2(\mathbb{R}^n)$, the remainder of the proposition is a consequence of the following more general fact.

Lemma 3.4. *Suppose Γ is any open subset of $\text{Sym}^2(\mathbb{R}^n)$ which is $\mathcal{P}$-monotone, i.e., $\Gamma + \mathcal{P} \subset \Gamma$. Then there exists a unique subequation $F \subset \text{Sym}^2(\mathbb{R}^n)$ with $\Gamma = \text{Int}F$, or otherwise said, $F = \overline{\Gamma}$ is a subequation, and Γ is its interior. Moreover, if $\Gamma \neq \emptyset, \text{Sym}^2(\mathbb{R}^n)$, then $F \neq \emptyset, \text{Sym}^2(\mathbb{R}^n)$.*

Proof. If $A \in F \equiv \overline{\Gamma}$ and $P \geq 0$, then $A = \lim_{j\to\infty} A_j$, $A_j \in \Gamma$ and hence $A + P = \lim_{j\to\infty}(A_j + P)$ with $A_j + P \in \Gamma$, that is, the closure F of Γ is $\mathcal{P}$-monotone, i.e., F is a subequation.

Now Γ is an open set $\subset F$, hence $\Gamma \subset \text{Int}F$. Finally, suppose $A \in \text{Int}F$. If $A \notin \Gamma$, then $(A - \text{Int}\mathcal{P}) \cap \Gamma = \emptyset$. Otherwise, $A - P \in \Gamma$, $P > 0 \Rightarrow A \in \Gamma$. Since $A - \text{Int}\mathcal{P}$ and Γ are open disjoint sets, $A - \text{Int}\mathcal{P}$ and $F = \overline{\Gamma}$ are disjoint. However, $A \in \text{Int}F \Rightarrow A - \epsilon I \in F$ for $\epsilon > 0$ small, which contradicts this intersections being empty. ∎

Branches

Let $\lambda_1(A) \leq \cdots \leq \lambda_n(A)$, or simply $\lambda_1 \leq \cdots \leq \lambda_n$, denote the ordered eigenvalues of $A \in \text{Sym}^2(\mathbb{R}^n)$. Recall that the kth branch of the Monge-Ampère equation $\det(A) = 0$ is the subequation $\mathbf{\Lambda}_k$ defined by

$$\mathbf{\Lambda}_k \;\equiv\; \{A : \lambda_k(A) \geq 0\} \qquad k = 1, ..., n. \qquad (3.4)$$

This construction extends to general equations $\mathfrak{g}(A) = 0$ where $\mathfrak{g}(A)$ is a degree m homogeneous polynomial on $\text{Sym}^2(\mathbb{R}^n)$ which is Gårding hyperbolic in the direction of the identity I (that is, all roots of $\mathfrak{g}(tI + A)$ are real for $A \in \text{Sym}^2(\mathbb{R}^n)$). The negatives of these roots are called the *Gårding* $\mathfrak{g}$-*eigenvalues.* The ordered $\mathfrak{g}$-eigenvalues $\lambda_1^{\mathfrak{g}}(A) \leq \cdots \leq \lambda_m^{\mathfrak{g}}(A)$ determine the kth branches $\mathbf{\Lambda}_k^{\mathfrak{g}}$ of the equation $\mathfrak{g}(A) = 0$ by

$$\mathbf{\Lambda}_k^{\mathfrak{g}} \;\equiv\; \{A : \lambda_k^{\mathfrak{g}}(A) \geq 0\} \qquad k = 1, ..., m. \qquad (3.5)$$

The first (or principle) branch is the closure of the open convex cone Γ defined by $\lambda_k^{\mathfrak{g}}(A) > 0$ for all k. This open cone, $\Gamma = \mathrm{Int}\boldsymbol{\Lambda}_1^{\mathfrak{g}}$, is called the **Gårding cone** for $\mathfrak{g}$, and $\overline{\Gamma} = \boldsymbol{\Lambda}_1^{\mathfrak{g}}$ is the **closed Gårding cone** for $\mathfrak{g}$.

Two cases of this construction are pertinent to understanding strict boundary convexity for the Special Langrangian potential equation. The first is the branches

$$\boldsymbol{\Lambda}_1 \subset \boldsymbol{\Lambda}_2 \subset \cdots \subset \boldsymbol{\Lambda}_n \tag{3.6}$$

of the Monge-Ampère equation $\mathfrak{g}(A) \equiv \det(A) = \sigma_n(A) = 0$. Here the $\mathfrak{g}$-eigenvalues of A are just the standard eigenvalues $\lambda_1, ..., \lambda_n$ of A. The second is the set of branches

$$\boldsymbol{\Lambda}_1^{\sigma_{n-1}} \subset \boldsymbol{\Lambda}_2^{\sigma_{n-1}} \subset \cdots \subset \boldsymbol{\Lambda}_{n-1}^{\sigma_{n-1}} \tag{3.7}$$

of the equation $\mathfrak{g}(A) \equiv \sigma_{n-1}(A) = 0$ (where σ_k is the kth elementary symmetric function of the eigenvalues of A).

The second case is complicated by the fact that the σ_{n-1}-eigenvalues, $\lambda_k^{\sigma_{n-1}}(A)$, cannot be computed in terms of the standard σ_n-eigenvalues $\lambda_1, ..., \lambda_n$ of A. Note that for any hyperbolic polynomial $\mathfrak{g}$, after renormalization, we have

$$\mathfrak{g}(tI + A) = t^m + \sigma_1^{\mathfrak{g}}(A)t^{m-1} + \cdots + \sigma_{m-1}^{\mathfrak{g}}(A)t + \sigma_m^{\mathfrak{g}}(A)$$

which defines the $\sigma_k^{\mathfrak{g}}(A)$'s. As a result we have

$$\sigma_{m-1}^{\mathfrak{g}}(A) = \frac{1}{m}\frac{d}{dt}\mathfrak{g}(tI + A)\big|_{t=0},$$

so the eigenvalues of $\sigma_{m-1}^{\mathfrak{g}}(A)$ are the critical points of $\mathfrak{g}(tI + A)$ which is $\det(tI + A)$ in our case.

Although the σ_{n-1}-eigenvalues, $\lambda_k^{\sigma_{n-1}}(A)$, cannot be computed in terms of the standard eigenvalues of A, the condition $\lambda_k^{\sigma_{n-1}}(A) \geq 0$ can be described by inequalities involving these eigenvalues. This key result, Proposition 4.5, was stated in the introduction and is proved near the end of Section 4.

Some General Results on the Pure Second-Order Dirichlet Problem

Here we recall what is known regarding the Dirichlet problem for an arbitrary subequation $\mathbf{F} \subset \mathrm{Sym}^2(\mathbb{R}^n)$ (defined at the beginning of this section). The results all apply to the equation $\mathbf{F}_\theta$. However, in Section 4 we get finer results for $\mathbf{F}_\theta$ by using Theorem 4.1 to implement the general results here.

Suppose Ω is a bounded domain in $\mathbb{R}^n$, and $X \subset \mathbb{R}^n$ is an arbitrary open subset.

Definition 3.5. A function $h \in C(X)$ is $\partial\mathbf{F}$-**harmonic** if h is $\mathbf{F}$-subharmonic and $-h$ is $\widetilde{\mathbf{F}}$-subharmonic where $\widetilde{\mathbf{F}} = \sim (-\mathrm{Int}\mathbf{F})$ is the dual subequation. (Note that $\partial\mathbf{F} = \mathbf{F} \cap (-\widetilde{\mathbf{F}})$.)

Definition 3.6. We say that **existence for the (DP) for $\partial \mathbf{F}$ holds on** Ω if for all prescribed boundary functions $\varphi \in C(\partial \Omega)$ there exists $h \in C(\overline{\Omega})$ satisfying

  (a) $h\big|_{\Omega}$ is $\partial \mathbf{F}$-harmonic, and

  (b) $h\big|_{\partial \Omega} = \varphi$.

Definition 3.7. We say that **uniqueness for the (DP) for $\partial \mathbf{F}$ holds on** Ω if for all prescribed boundary functions $\varphi \in C(\partial \Omega)$ there exists at most one $h \in C(\overline{\Omega})$ satisfying (a) and (b).

Consider also the following stronger versions of existence and uniqueness.

Definition 3.8. If for all $\varphi \in C(\overline{\Omega})$ the Perron function

$$h(x) \equiv \sup\{u(x) : u \in \mathrm{USC}(\overline{\Omega}), \ u \text{ is } \mathbf{F}\text{-subharmonic, and } u\big|_{\partial \Omega} \leq \varphi\}$$

is in $C(\overline{\Omega})$ and satisfies (a) and (b), then we say that **Perron existence holds for $\partial \mathbf{F}$ on** Ω.

Definition 3.9. If for all $u, v \in \mathrm{USC}(\overline{\Omega})$ with $u\big|_{\Omega}$ $\mathbf{F}$-subharmonic and $v\big|_{\Omega}$ $\widetilde{\mathbf{F}}$-subharmonic,

$$u + v \ \leq \ 0 \quad \text{on } \partial \Omega \qquad \Rightarrow \qquad u + v \ \leq \ 0 \quad \text{on } \overline{\Omega},$$

then we say that **comparison holds for $\mathbf{F}$ on** Ω.

Obviously Perron existence implies existence, and comparison implies uniqueness.

In [DD] comparison was shown to always hold.

THEOREM 3.10. (Comparison). *For all bounded domains $\Omega \subset \mathbb{R}^n$ and $u, v \in \mathrm{USC}(\overline{\Omega})$ with $u\big|_{\Omega}$ $\mathbf{F}$-subharmonic and $v\big|_{\Omega}$ $\widetilde{\mathbf{F}}$-subharmonic,*

$$u + v \ \leq \ 0 \quad \text{on } \partial \Omega \qquad \Rightarrow \qquad u + v \ \leq \ 0 \quad \text{on } \overline{\Omega}.$$

(See Remark 4.9 in [DD] for the proof that the definitions of $\mathbf{F}$ and $\widetilde{\mathbf{F}}$-subharmonicity agree with the appropriate viscosity definitions.)

Theorem 3.10 applies to the SL-potential equation $\mathbf{F}_\theta$ for arbitrary phase θ (see (3.1b)), extending the result of [CNS] for $(n-1)\frac{\pi}{2} < \theta < n\frac{\pi}{2}$, and settling the comparison/uniqueness question in the affirmative for all bounded domains.

A second proof of Theorem 3.10 was given later in [DDR].

This leaves the existence question for $\mathbf{F}$, which is also covered by the following result of [DD].

THEOREM 3.11. (Perron Existence). *Suppose that Ω is a bounded domain with smooth boundary $\partial\Omega$. If, at each point of $\partial\Omega$, the boundary is both*

$$\mathbf{F}\text{-strictly convex, and } \widetilde{\mathbf{F}}\text{-strictly convex,} \tag{3.8}$$

then Perron existence for $\partial\mathbf{F}$ holds on Ω.

The definition of strict convexity in (3.8) has many equivalent formulations. The key is the asymptotic interior $\text{Int}\,\overrightarrow{\mathbf{F}}$ of $\mathbf{F}$ (see Definition 3.2).

Here are two of the equivalent definitions of strict $\mathbf{F}$-convexity for $\partial\Omega$. Let $\mathrm{II}_{x,\partial\Omega}$ denote the second fundamental form of $\partial\Omega$ with respect to the interior unit normal $n = n_x$, and let P_n be orthogonal projection onto the line $\mathbb{R}\cdot n$. Then for each $x \in \partial\Omega$, **strict F-convexity** is the requirement that

$$\mathrm{II}_{x,\partial\Omega} + tP_n \ \in \ \text{Int}\,\overrightarrow{\mathbf{F}} \quad \text{for } t \gg 0, \tag{3.9a}$$

This definition is equivalent to the following.

$$\begin{aligned} &\exists\, \rho \in C^\infty(\overline{\Omega}) \text{ with } \Omega = \{\rho < 0\}, \text{ and } \rho = 0 \text{ and } \nabla\rho \neq 0 \text{ on } \partial\Omega, \\ &\qquad \text{such that} \quad D_x^2\rho \in \text{Int}\,\overrightarrow{\mathbf{F}} \ \forall x \in \overline{\Omega}. \end{aligned} \tag{3.9b}$$

See [DD] Lemma 5.3 and Corollary 5.4 for the equivalence of (3.9a) and (3.9b).

Summarizing by combining Theorems 3.10 and 3.11, we have for a general subequation $\mathbf{F} \subset \text{Sym}^2(\mathbb{R}^n)$ the following.

THEOREM 3.12. (Dirichlet Problem). *Suppose that Ω is a bounded domain with C^∞ boundary $\partial\Omega$ with is both $\mathbf{F}$ and $\widetilde{\mathbf{F}}$ strictly convex. Then both Perron existence and comparison hold for $\mathbf{F}$ on Ω. In particular, both existence and uniqueness hold for the $\mathbf{F}$ Dirichlet problem on Ω*

In particular all this applies to the SL potential equation of arbitrary phase. Now we come to the main new result of this paper.

4. Computing the Asymptotic Interior of $\mathbf{F}_\theta$

Phases (or Values) of the Special Langrangian Potential Operator

We now consider the operator $f(A) \equiv \text{tr}\{\arctan(A)\}$ defined on $\mathbf{F} \equiv \text{Sym}^2(\mathbb{R}^n)$. This operator f has values precisely in the open interval $(-n\frac{\pi}{2}, n\frac{\pi}{2})$. There are $n-1$

Special Phases(orValues) : $\qquad \theta_k \ = \ (n-2k)\dfrac{\pi}{2}, \quad k = 1, ..., n-1. \tag{4.1}$

Removing these $n-1$ special values, the remaining set of values is the disjoint union of n open

Phase Intervals : $I_k = \left((n - 2k)\dfrac{\pi}{2}, \ (n - 2(k-1))\dfrac{\pi}{2} \right), \ k = 1, ..., n.$

$$(4.2)$$

THEOREM 4.1. *The asymptotic subequation $\overrightarrow{\mathbf{F}}_\theta$ of $\mathbf{F}_\theta$, for $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$, is given as follows.*

(1)   *If $\theta \in I_k \ (k = 1, ..., n)$, then*

$$\overrightarrow{\mathbf{F}}_\theta = \mathbf{\Lambda}_k.$$

(2)   *If $\theta_k \ (k = 1, ..., n-1)$ is a special value, then*

$$\overrightarrow{\mathbf{F}}_{\theta_k} = \mathbf{\Lambda}_k^{\sigma_{n-1}}.$$

For the proof of both parts we will need the asymptotic expansion for $f(tA)$ as $t \to \infty$. For the proof of part (2) we will also need Proposition 4.5 below describing $\mathbf{\Lambda}_k^{\sigma_{n-1}}$. Define

$$q(A) = \text{the number of strictly negative eigenvalues of } A. \qquad (4.3)$$

Lemma 4.2. *Suppose A is non-degenerate $(\sigma_n(A) \neq 0)$. Then*

$$
\begin{aligned}
f(tA) &= \text{tr}\{\arctan(tA)\} \\
&= (n - 2q(A))\frac{\pi}{2} - \frac{1}{t}\frac{\sigma_{n-1}(A)}{\sigma_n(A)} + O\left(\frac{1}{t^3}\right) \quad \text{as } t \to \infty.
\end{aligned}
\qquad (4.4)
$$

Corollary 4.3. *Suppose $\sigma_n(A) \neq 0$. Then*

(1)

$$\lim_{t \to \infty} f(tA) = (n - 2q(A))\frac{\pi}{2}, \qquad (4.5)$$

and if also $\sigma_{n-1}(A) \neq 0$, then

(2)   *$f(tA)$ either strictly decreases to $(n - 2q(A))\frac{\pi}{2}$ or strictly increases to $(n - 2q(A))\frac{\pi}{2}$ depending on whether $\sigma_{n-1}(A)$ and $\sigma_n(A)$ have opposite signs or the same sign respectively.*

Proof of Lemma 4.2. The asymptotic expansion for the $\arctan t$ as $t \to \infty$ is

$$\arctan(t) = \frac{\pi}{2} - \frac{1}{t} + \frac{1}{3t^3} + \cdots \quad \text{as } t \to \infty. \qquad (4.6)$$

(Note that $\arctan(t)$ and $-\arctan(1/t)$ have the same derivative so that $\arctan(t) = \pi/2 - \arctan(1/t)$, and for $s > 0$ small, $\arctan(s) = s - \frac{1}{3}s^3 + \cdots$.)

The number of strictly positive eigenvalues of A is $n - q(A)$ since A has no zero eigenvalues. Therefore,

$$f(tA) \; = \; \mathrm{tr}\{\arctan(tA)\} \; = \; \sum_{k=1}^{n} \mathrm{tr}\{\arctan(t\lambda_k)\}$$

$$= \; (n - 2q(A))\frac{\pi}{2} \; - \; \frac{1}{t}\left(\sum_{k=1}^{n}\frac{1}{\lambda_k}\right) + O\left(\frac{1}{t^3}\right).$$

Since

$$\sum_{k=1}^{n}\frac{1}{\lambda_k} \; = \; \frac{\sigma_{n-1}(A)}{\sigma_n(A)},$$

this completes the proof. ∎

Because of Definition 3.2 and Proposition 3.3, by taking closures/interiors we have the following equivalent version of Theorem 4.1.

Theorem 4.1′.

   $(1)'$ If $\theta \in I_k$ $(k = 1, ..., n)$, then

$$\overrightarrow{\mathrm{Int}}\,\mathbf{F}_\theta \; = \; \mathrm{Int}\mathbf{\Lambda}_k.$$

   $(2)'$ If θ_k $(k = 1, ..., n-1)$ is a special value, then

$$\overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k} \; = \; \mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}.$$

We will make use of the following equivalent ways of defining the kth branch of the equation $\det A = 0$.

Lemma 4.4. *One has that* $A \in \mathbf{\Lambda}_k \iff \lambda_k(A) \geq 0 \iff q(A) \leq k - 1 \iff q(A) < k \iff (n - 2q(A))\frac{\pi}{2} \geq (n - 2(k-1))\frac{\pi}{2} \iff (n - 2q(A))\frac{\pi}{2} > (n - 2k)\frac{\pi}{2}$. *One also has:* $A \in \mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k \iff k \leq q(A) \leq k$, *i.e.,* $q(A) = k$.

Next note that for each $A \in \mathrm{Sym}^2(\mathbb{R}^n)$, $\sigma_n(A - \epsilon I)$ and $\sigma_{n-1}(A - \epsilon I)$ are polynomials in ϵ, so that

$$\{\epsilon > 0 : \sigma_n(A - \epsilon I) = 0\} \quad \text{and} \quad \{\epsilon > 0 : \sigma_{n-1}(A - \epsilon I) = 0\} \quad \text{are finite.} \quad (4.7)$$

Proof of Theorem 4.1′ (1)′. Now assume $\theta \in I_k$, i.e., $(n - 2k)\frac{\pi}{2} < \theta < (n - 2(k-1))\frac{\pi}{2}$.

If $A \in \mathrm{Int}\mathbf{\Lambda}_k$, then $A_\epsilon \equiv A - \epsilon I \in \mathbf{\Lambda}_k$ for $\epsilon > 0$ small. By Lemma 4.4, we have $A_\epsilon \in \mathbf{\Lambda}_k \iff (n - 2(k-1))\frac{\pi}{2} \leq (n - 2q(A_\epsilon))\frac{\pi}{2}$. Hence, $\theta < (n - 2q(A_\epsilon))\frac{\pi}{2}$. We can assume that A_ϵ is non-degenerate by (4.7), so we can apply Corollary 4.3 to obtain

$$\theta \; < \; \lim_{t\to\infty} f(tA_\epsilon).$$

In particular, there exists t_0 such that $f(t(A - \epsilon I)) \geq \theta$ for all $t \geq t_0$ or equivalently $t(A - \epsilon I) \in \mathbf{F}_\theta$ for all $t \geq t_0$. By Definition (3.2a) this proves $A \in \overrightarrow{\mathrm{Int}}\, \mathbf{F}_\theta$.

Conversely, suppose $A \in \overrightarrow{\mathrm{Int}}\, \mathbf{F}_\theta$. Then by Definition (3.2a), there exists $\epsilon > 0$ and t_0 such that $f(t(A - \epsilon I)) \geq \theta$ for all $t \geq t_0$, but $\theta \in I_k \Rightarrow (n - 2k)\frac{\pi}{2} < \theta$. By (4.7) we can assume $\sigma_n(A - \epsilon I) \neq 0$, so Corollary 4.3(1) applies to yield

$$(n - 2k)\frac{\pi}{2} \ < \ \theta \ \leq \ \lim_{t \to \infty} f(tA_\epsilon) \ = \ (n - 2q(A_\epsilon))\frac{\pi}{2}.$$

By Lemma 4.4 this implies $A_\epsilon = A - \epsilon I \in \mathbf{\Lambda}_k$. Hence $A \in \mathrm{Int}\,\mathbf{\Lambda}_k$. This proves $(1)'$ and hence (1). ∎

To prove Part $(2)'$ we use Proposition 4.5 below.

Describing the Branches $\mathbf{\Lambda}_k$ and $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ in Terms of Roots and Critical Points

The kth branch $\mathbf{\Lambda}_k$ of $\det(A)$ was defined in (3.4) as the set $\{\lambda_k(A) \geq 0\}$, $k = 1, ..., n$. The negatives of the eigenvalues of A will be referred to as the *roots* of A. More precisely, we adopt the following definitions.

$$\text{Let} \quad \ell \equiv n - k \qquad \text{for } k = 1, ..., n \quad \text{and then}$$
$$\text{let} \quad r_{\ell+1} \overset{\mathrm{def}}{=} -\lambda_k, \qquad \text{for } \ell + 1 = 1, ..., n. \tag{4.8}$$

Consequently,

$$r_1 \leq \cdots \leq r_{\ell+1} \leq \cdots \leq r_n, \qquad \ell = 0, ..., n - 1.$$

are the **ordered roots**. With this notation

$$\mathbf{\Lambda}_k \ = \ \{A : \lambda_k(A) \geq 0\} \ = \ \{A : r_{\ell+1}(A) \leq 0\} \qquad \text{where } k + \ell = n \quad (4.9a)$$

and

$$\mathbf{\Lambda}_{k+1} \ = \ \{A : \lambda_{k+1}(A) \geq 0\} \ = \ \{A : r_\ell(A) \leq 0\} \qquad \text{where } k + \ell = n \tag{4.9b}$$

In addition, their interiors are given by the corresponding strict inequalities, and their boundaries by equality.

The roots $r_j(A)$ are the roots of the monic polynomial $p_A(t)$ (or simply $p(t)$) defined by

$$p(t) \ = \ \det(tI + A) \ = \ t^n + \sigma_1(A)t^{n-1} + \cdots + \sigma_n(A)$$
$$= \ \prod_{k=1}^{n}(t + \lambda_k) \ = \ \prod_{\ell=1}^{n}(t - r_\ell) \tag{4.10}$$

As noted in Section 3

$$\sigma_{n-1}(tI + A) \ = \ \frac{1}{n}\frac{d}{dt}\det(tI + A) \ = \ \frac{1}{n}p'(t).$$

Hence the roots of A for σ_{n-1} are the *critical points* of $p(t) = \det(tI + A)$, which we denote by $c_1(A) \le \cdots \le c_\ell(A) \le \cdots \le c_{n-1}(A)$. (It will not be necessary to label their negatives which are the σ_{n-1}-eigenvalues of A.)

The same reasoning used to prove (4.9) provides a description of the kth branch of $\sigma_{n-1} = 0$ (now the degree is $n - 1$ instead of n) in terms of the ordered critical points.

$$\mathbf{\Lambda}_k^{\sigma_{n-1}} = \{A : c_\ell(A) \le 0\} \qquad k + \ell = n \ \text{ and } \ k = 1, ..., n - 1. \qquad (4.11)$$

Again,strict inequality defines the interiors and equality defines the boundaries.

With the translations above from eigenvalues to roots and critical points, we will make use of the following three elementary facts.

Fact 1.

$$r_1 \le c_1 \le r_2 \le \cdots \le r_\ell \le c_\ell \le r_{\ell+1} \le \cdots \le c_{n-1} \le r_n.$$

This fact implies the nesting

$$\mathbf{\Lambda}_1 \subset \mathbf{\Lambda}_1^{\sigma_{n-1}} \subset \cdots \mathbf{\Lambda}_k \subset \mathbf{\Lambda}_k^{\sigma_{n-1}} \subset \mathbf{\Lambda}_{k+1} \subset \cdots \subset \mathbf{\Lambda}_n, \quad 1 \le k \le n-1. \ (4.12)$$

The second elementary fact eliminates all but two of the possibilities for $r_\ell \le c_\ell \le r_{\ell+1}$.

Fact 2. Either $r_\ell < c_\ell < r_{\ell+1}$ or $r_\ell = c_\ell = r_{\ell+1}$, $\quad$ for $\ell = 1, ..., n - 1$.

The third elementary fact is crucial.

Fact 3. Assume $r_\ell < c_\ell < r_{\ell+1}$, Then

$$p(t)p'(t) > 0 \ \text{ on } \ (r_\ell, c_\ell) \qquad \text{and} \qquad p(t)p'(t) < 0 \ \text{ on } \ (c_\ell, r_{\ell+1}).$$

Proof of Fact 3. Note that $p(t) \ne 0$ on $(r_\ell, r_{\ell+1})$ and $p'(t) \ne 0$ on both (r_ℓ, c_ℓ) and $(c_\ell, r_{\ell+1})$. In particular, $p(c_\ell) \ne 0$. If $p(c_\ell) > 0$, then $p(t)$ increases from 0 to $p(c_\ell)$ on (r_ℓ, c_ℓ), and hence $p(t)p'(t) > 0$ on (r_ℓ, c_ℓ). If $p(c_\ell) < 0$, then $p(t)$ decreases from 0 to $p(c_\ell)$ on (r_ℓ, c_ℓ), and hence again $p(t)p'(t) > 0$ on (r_ℓ, c_ℓ). The proof that $p(t)p'(t) < 0$ on $(c_\ell, r_{\ell+1})$ is similar. ∎
Each of the sets $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ and $\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}$ can be divided into the disjoint union of the part in $\mathbf{\Lambda}_k$ and the part in the complement of $\mathbf{\Lambda}_k$. We now compute these pieces.

Proposition 4.5a. (The Parts that Lie in $\mathbf{\Lambda}_k$). *For all $k = 1, ..., n$ we have:*

(i) $\mathbf{\Lambda}_k^{\sigma_{n-1}} \cap \mathbf{\Lambda}_k \ = \ \mathbf{\Lambda}_k,$

(ii) $(\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}) \cap \mathbf{\Lambda}_k \ = \ (\mathrm{Int}\mathbf{\Lambda}_{k+1}) \cap \mathbf{\Lambda}_k,$

Proof. By (4.12) we have $\mathbf{\Lambda}_k \subset \mathbf{\Lambda}_k^{\sigma_{n-1}}$, and so (i) follows.

For (ii) note first that by (4.12) we have $\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}} \subset \mathrm{Int}\mathbf{\Lambda}_{k+1}$ and therefore that $(\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}) \cap \mathbf{\Lambda}_k \subset (\mathrm{Int}\mathbf{\Lambda}_{k+1}) \cap \mathbf{\Lambda}_k$. For the equality in (ii), assume $A \in (\mathrm{Int}\mathbf{\Lambda}_{k+1}) \cap \mathbf{\Lambda}_k = \{r_\ell < 0\} \cap \{r_{\ell+1} \leq 0\}$. By Fact 1 we have $r_\ell \leq c_\ell \leq r_{\ell+1} \leq 0$. Now $c_\ell = 0$ is impossible, because this would imply $c_\ell = r_{\ell+1}$, and by Fact 2 this would imply that $r_\ell = c_\ell = r_{\ell+1} = 0$, which contradicts the assumption that $r_\ell < 0$. This proves that $r_\ell < c_\ell < r_{\ell+1} \leq 0$, which implies that $A \in \mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}} = \{c_\ell < 0\}$.   ∎

Now we compute the $(\sim \mathbf{\Lambda}_k)$-part of $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ and $\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}$.

Proposition 4.5b. (The Parts that Lie in $\sim \mathbf{\Lambda}_k$). *For all $k = 1, ..., n$ we have:*

(i) $\mathbf{\Lambda}_k^{\sigma_{n-1}} \cap (\sim \mathbf{\Lambda}_k) \ = \ (\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{\sigma_n \sigma_j < 0\}$

where j is the largest integer $0 \leq j \leq n-1$ with $\sigma_j(A) \neq 0$ (with $\sigma_0(A) \overset{\mathrm{def}}{=} 1$).

(ii) $(\mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}) \cap (\sim \mathbf{\Lambda}_k) \ = \ (\mathrm{Int}\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{\sigma_n \sigma_{n-1} < 0\}.$

Proof. We begin with (i). Since $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ is contained in $\mathbf{\Lambda}_{k+1}$, the $\sim \mathbf{\Lambda}_k$-part of $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ is equal to its intersection with $\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k = \{r_\ell \leq 0 < r_{\ell+1}\}$. Since $r_\ell \neq r_{\ell+1}$ here, we have from Fact 2 that

$$\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k \ = \ \{r_\ell \leq 0 < r_{\ell+1}\} \cap \{r_\ell < c_\ell < r_{\ell+1}\}. \tag{4.13}$$

Intersecting with $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ we have

$$E_k \overset{\mathrm{def}}{=} \mathbf{\Lambda}_k^{\sigma_{n-1}} \cap (\sim \mathbf{\Lambda}_k) = \mathbf{\Lambda}_k^{\sigma_{n-1}} \cap (\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) = \{r_\ell < c_\ell \leq 0 < r_{\ell+1}\} \tag{4.14}$$

In particular 0 is not a root of $p(t)$ so that

$$p(0) \ = \ \sigma_n(A) \ \neq \ 0 \qquad \text{for } \ A \in E_k. \tag{4.15}$$

Now by Fact 3 we have

$$E_k \ = \ (\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{A : p_A(t)p'_A(t) < 0 \ \text{ on } \ (c_\ell, r_{\ell+1})\}. \tag{4.16}$$

Set $\sigma_0(A) \overset{\mathrm{def}}{=} 1$ and let j_A (or j) denote the largest integer $0 \leq j \leq n-1$ with $\sigma_j(A) \neq 0$. (4.17)

Then we have the Taylor expansion

$$p_A(t) = \sigma_n(A) + t^{n-j}\sigma_j(A) + t^{n-j+1}\sigma_{j-1}(A) + \cdots + t^n.$$

Consequently, $p_A(t)p'_A(t) < 0$ for $0 < t$ small $\iff \sigma_n(A)\sigma_j(A) < 0$. By (4.15) we have that $\sigma_n(A) \neq 0$. This proves Part (i).

Note: If $c_\ell < 0$, then $0 \in (c_\ell, r_{\ell+1})$ so that $p(t)p'(t) < 0$ on $(c_\ell, r_{\ell+1})$ is equivalent to $\sigma_n(A)\sigma_{n-1}(A) = p(0)p'(0) < 0$. The expansion is only needed for the proof if $c_\ell = 0$.

For Part (ii) note that since $\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}} \subset \text{Int}\boldsymbol{\Lambda}_{k+1}$, we have

$$\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}} \cap (\sim \boldsymbol{\Lambda}_k) = \text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}} \cap (\text{Int}\boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k),$$

which equals

$$\{c_\ell < 0\} \cap \{r_\ell < 0 < r_{\ell+1}\}.$$

By Fact 2, $r_\ell \neq r_{\ell+1}$ implies $r_\ell < c_\ell < r_{\ell+1}$. Therefore,

$$(\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}) \cap (\sim \boldsymbol{\Lambda}_k) = \{r_\ell < c_\ell < 0 < r_{\ell+1}\}$$

This is a subset of E_k defined above. Since by (4.16) we have

$$E_k = (\boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k) \cap \{A : p_A(t)p'_A(t) < 0 \text{ on } (c_\ell, r_{\ell+1})\}$$

and since $0 \in (c_\ell, r_{\ell+1})$ we have $p_A(0)p'_A(0) = \sigma_n(A)\sigma_{n-1}(A) < 0$, proving that

$$(\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}) \cap (\sim \boldsymbol{\Lambda}_k) \subset (\text{Int}\boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k) \subset (\text{Int}\boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k) \cap \{\sigma_n\sigma_{n-1} < 0\}.$$

Now suppose A is an element of the R.H.S., i.e., assume $r_\ell < 0 < r_{\ell+1}$, so by Fact 2, $r_\ell < c_\ell < r_{\ell+2}$ and $p(0)p'(0) < 0$. Then by Fact 3, $0 \in (c_\ell, r_{\ell+1})$ proving that $c_\ell < 0$, i.e., that $A \in \text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$. This proves Part (ii).

Combining (i) and (ii) we have that the piece of the boundary $\partial\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$ contained in $\sim \boldsymbol{\Lambda}_k$ is given by (iii). ∎

To complete the proof of Theorem 4.1′ we must prove (2)′.

Proof of Theorem 4.1′ (2)′. First we prove that $\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}} \subset \overrightarrow{\text{Int}}\,\mathbf{F}_{\theta_k}$. If $A \in \text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$, then for $\epsilon > 0$ small, $A_\epsilon \equiv A - \epsilon I \in \text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$. Proposition 4.5 part (ii) gives two possibilities for A_ϵ. In both cases we will show that $A \in \overrightarrow{\text{Int}}\,\mathbf{F}_{\theta_k}$.

First suppose A_ϵ is in the $\boldsymbol{\Lambda}_k$ piece of $\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$. Then $A_{\frac{\epsilon}{2}} = A_\epsilon + \frac{\epsilon}{2}I \in \text{Int}\boldsymbol{\Lambda}_k$. By (1)′, $A_{\frac{\epsilon}{2}} \in \overrightarrow{\text{Int}}\,\mathbf{F}_\theta$ for all $\theta \in I_k$. But θ_k is the left endpoint of I_k. Hence, picking $\theta \in I_k$, we have that $\theta_k < \theta$ so that $\overrightarrow{\text{Int}}\,\mathbf{F}_\theta \subset \text{Int}\,\overrightarrow{\mathbf{F}}_{\theta_k}$, proving that $A_{\frac{\epsilon}{2}}$, and hence $A = A_{\frac{\epsilon}{2}} + \frac{\epsilon}{2}I$ is in $\overrightarrow{\text{Int}}\,\mathbf{F}_{\theta_k}$.

Secondly, suppose A_ϵ is in the $\sim \boldsymbol{\Lambda}_k$-piece of $\text{Int}\boldsymbol{\Lambda}_k^{\sigma_{n-1}}$. Then by Proposition 4.5b(ii) $A_\epsilon \in (\text{Int}\boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k) \cap \{\sigma_n\sigma_{n-1} < 0\}$. Since $A_\epsilon \in \boldsymbol{\Lambda}_{k+1} \sim \boldsymbol{\Lambda}_k$, Lemma 4.4 says that $q(A) = k$. Since $\sigma_n(A_\epsilon)\sigma_{n-1}(A_\epsilon) < 0$, we have by Corollary 4.3(2), that $f(tA_\epsilon)$ strictly decreases to $(n - 2q(A_\epsilon))\frac{\pi}{2} = (n - 2k)\frac{\pi}{2}$

as $t \nearrow \infty$. Thus $tA_\epsilon \in \mathbf{F}_{\theta_k}$ for all $t > 0$, which, by Definition 3.2 of $\overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k}$, proves that $A \in \overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k}$.

It remains to show that $\overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k} \subset \mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}$, so suppose $A \in \overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k}$. Then by definition we have $\liminf_{t\to\infty} f(tA_\epsilon) \geq \theta_k$ for some $\epsilon > 0$ small. By (4.7) we can consider $\epsilon > 0$ with $\sigma_{n-1}(A_\epsilon) \neq 0$ and $\sigma_n(A_\epsilon) \neq 0$, and apply Lemma 4.2 to conclude that

$$\theta_k \;\equiv\; (n-2k)\frac{\pi}{2} \;\leq\; \liminf_{t\to\infty} f(tA_\epsilon) \;=\; (n-2q(A_\epsilon))\frac{\pi}{2}.$$

This is one of the equivalent ways of saying that $A_\epsilon \in \mathbf{\Lambda}_{k+1}$. By decreasing ϵ we have $A_\epsilon \in \mathrm{Int}\mathbf{\Lambda}_{k+1}$. If $A_\epsilon \in \mathbf{\Lambda}_k \cap (\mathrm{Int}\mathbf{\Lambda}_{k+1})$, then $A \in \mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}$ by Proposition 4.5a(ii). Otherwise, $A_\epsilon \in \mathrm{Int}\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k$, so by Lemma 4.4, $q(A_\epsilon) = k$. By Corollary 4.3(2), if $\sigma_{n-1}(A_\epsilon)$ and $\sigma_n(A_\epsilon)$ have the same sign, then $f(tA_\epsilon)$ strictly increases to $(n-2k)\frac{\pi}{2} = \theta_k$. This contradicts Definition 3.2 which says that $A \in \overrightarrow{\mathrm{Int}}\,\mathbf{F}_{\theta_k} \iff f(tA_\epsilon) \geq \theta_k \;\forall t \geq t_0$. Therefore, $\sigma_{n-1}(A_\epsilon)$ and $\sigma_n(A_\epsilon)$ have opposite signs, which proves that $A \in \mathrm{Int}\mathbf{\Lambda}_k^{\sigma_{n-1}}$ by Proposition 4.5b(ii).

This completes the proof of Theorems 4.1$'$ and 4.1.   ∎

From Theorem 4.1 and Proposition 4.5 we have the following.

THEOREM 4.6. *The interior of* $\mathbf{\Lambda}_k^{\sigma_{n-1}}$ *is given as follows.*

(1) *If* $\theta \in I_k$ *(*$k = 1, ..., n$*), then*

$$\mathrm{Int}\overrightarrow{\mathbf{F}}_\theta \;=\; \mathrm{Int}\mathbf{\Lambda}_k \;\equiv\; \{A \in \mathrm{Sym}^2(\mathbb{R}^n) : \lambda_k(A) > 0\}.$$

(2) *If* θ_k *(*$k = 1, ..., n-1$*) is a special value, then*

$$\mathrm{Int}\overrightarrow{\mathbf{F}}_{\theta_k} \;=\; \{\mathrm{Int}\mathbf{\Lambda}_{k+1} \cap \mathbf{\Lambda}_k\} \cup E_k^\star$$

where

$$E_k^\star \;\equiv\; (\mathrm{Int}\mathbf{\Lambda}_{k+1} \sim \mathbf{\Lambda}_k) \cap \{\sigma_{n-1}(A)\,\sigma_n(A) < 0\}$$

Second proof of Proposition 4.5 part (i) We give here a alternative proof which is based on Lemma A.1 in [HP2]. Let

$$p(t) \;=\; \prod_{k=1}^n (t + \lambda_k(A)) \;=\; t^n + \sigma_1(A)t^{n-1} + \sigma_2(A)t^{n-2}\cdots + \sigma_n(A)$$

be the monic polynomial associated to $A \in \mathrm{Sym}^2(\mathbb{R}^n)$ as above. Define $\sigma_0(A) = 1$ and set $\sigma(A) \equiv (1, \sigma_1(A), ..., \sigma_n(A))$. Let $\widetilde{\sigma(A)}$ denote the possibly shorter tuple where all the zero entries are removed. Define

$$\mathrm{Var}(\widetilde{\sigma(A)}) \;\equiv\; \text{the number of (strict) sign changes in } \widetilde{\sigma(A)}.$$

Lemma A.1. *The kth branch of $\{p = 0\}$ equals $\{A : \text{Var}(\widetilde{\sigma(A)}) \leq k - 1\}$. In particular, with $p(t) \equiv \det(tI + A)$,*

$$\Lambda_{k+1} \sim \Lambda_k \;=\; \{A : \text{Var}(\widetilde{\sigma(A)}) = k\}. \tag{4.18}$$

This Lemma also applies to the monic polynomial

$$\frac{1}{n}p'(t) \;\equiv\; t^{n-1} + \frac{n-1}{n}\sigma_1(A)t^{n-2} + \cdots + \frac{1}{n}\sigma_{n-1}(A)$$

proving that

$$\Lambda_k^{\sigma_{n-1}} \;\equiv\; \{A : \text{Var}(\widetilde{\alpha(A)}) \leq k - 1\} \tag{4.19}$$
$$\text{where} \quad \alpha(A) \equiv (1, \sigma_1(A), ..., \sigma_{n-1}(A)).$$

(The coefficients in this polynomial $\frac{1}{n}p'(t)$ have been normalized in the definition of $\alpha(A)$, without changing their signs or their being zero.) Note that

$$\widetilde{\sigma(A)} \;=\; \begin{cases} \widetilde{\alpha(A)} & \text{if} \quad \sigma_n(A) = 0 \\ (\widetilde{\alpha(A)}, \sigma_n(A)) & \text{if} \quad \sigma_n(A) \neq 0 \end{cases} \tag{4.20}$$

In particular, $\text{Var}(\widetilde{\alpha(A)}) \leq \text{Var}(\widetilde{\sigma(A)}) \leq \text{Var}(\widetilde{\alpha(A)}) + 1$. This proves that $\Lambda_k \subset \Lambda_k^{\sigma_{n-1}} \subset \Lambda_{k+1}$ and hence Proposition 4.5a(i). To prove Proposition 4.5b(i) that $\Lambda_k^{\sigma_{n-1}} \cap (\Lambda_{k+1} \sim \Lambda_k) = \{A : \sigma_n(A) \neq 0 \text{ and } \sigma_j(A)\sigma_n(A) < 0\}$ first note that if $A \in \Lambda_k^{\sigma_{n-1}}$, i.e., $\text{Var}(\widetilde{\alpha(A)}) \leq k - 1$, then in order for $A \in \Lambda_{k+1} \sim \Lambda_k$, i.e., $\text{Var}(\widetilde{\sigma(A)}) = k$, one must have $\sigma_n(A) \neq 0$.

Now $\widetilde{\alpha(A)} = (1, ..., \sigma_j(A))$ where j is the largest integer $\leq n - 1$ such that $\sigma_j(A) \neq 0$ and $\sigma(A) = (1, ..., \sigma_j(A), \sigma_n(A))$ if $A \in \Lambda_{k+1} \sim \Lambda_k$. Now $A \in \Lambda_k^{\sigma_{n-1}} \cap (\Lambda_{k+1} \sim \Lambda_k) \iff \sigma_n(A) \neq 0$ and $\text{Var}(\widetilde{\sigma(A)}) = \text{Var}(\widetilde{\alpha(A)}) + 1$, so that $\sigma_n(A) \neq 0$, $\sigma_j(A) \neq 0$ and $\sigma_j(A)\sigma_n(A) < 0$. $\blacksquare$

5. The Refined Dirichlet Problem for $\mathbf{F}_\theta$

Theorem 3.12 recalled the general result which applies to the Dirichlet problem for the equation $\mathbf{F}_\theta$. In this section we will get a deeper result by using our explicitly computed asymptotic interiors for $\mathbf{F}_\theta$.

We begin with the following note. In general for the Dirichlet problem we require that the boundary be strictly $\mathbf{F}$ and $\widetilde{\mathbf{F}}$ convex at each point. (See Theorem 3.12 for example.) However, for the subequation $\mathbf{F}_\theta$ only one of these is necessary. Since $\arctan x$ is odd, it is easy to compute that the dual

$$\widetilde{\mathbf{F}_\theta} \;=\; \mathbf{F}_{-\theta}, \quad \text{and hence} \tag{5.1}$$

$$\overrightarrow{\widetilde{\mathbf{F}_\theta}} \;=\; \overrightarrow{\mathbf{F}}_{-\theta}. \tag{5.2}$$

(Recall the definition of strict $\mathbf{F}$-convexity from (3.9).)

If $0 \leq \theta < n\frac{\pi}{2}$, then

$$\mathbf{F}_{-\theta} \supset \mathbf{F}_{\theta}, \quad \text{and hence} \quad \overrightarrow{\widetilde{\mathbf{F}}_{\theta}} = \overrightarrow{\mathbf{F}}_{-\theta} \supset \overrightarrow{\mathbf{F}}_{\theta}, \tag{5.3}$$

that is,

$$\partial\Omega \text{ is strictly } \mathbf{F}_{\theta}\text{-convex} \quad \Rightarrow \quad \partial\Omega \text{ is strictly } \widetilde{\mathbf{F}}_{\theta}\text{-convex} \tag{5.4}$$

Hence,

> in applying Theorem 3.11 or Theorem 3.12 to $\mathbf{F} = \mathbf{F}_{\theta}$,
> one need only hypothesize that $\partial\Omega$ is strictly $\mathbf{F}_{|\theta|}$-convex. $\tag{5.5}$

Note that since $\widetilde{\mathbf{F}}_{\theta} = \mathbf{F}_{-\theta}$, we may assume in analyzing the Dirichlet problem, that $\theta \geq 0$. For if $\theta < 0$, we simply consider the equivalent problem given by replacing $\mathbf{F}_{\theta}$ with $\widetilde{\mathbf{F}}_{\theta}$.

Combining these remarks and Theorem 4.1 with Theorem 3.12 yields one of the main results of this paper – part (b) below. Part (a) follows from Theorem 3.10.

THEOREM 5.1.

(a) Comparison holds for $\mathbf{F}_{\theta}$ for all $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$ on all bounded domains $\Omega \subset \mathbb{R}^n$.

(b) Suppose Ω has a smooth boundary $\partial\Omega$, and assume w.l.o.g. that $\theta \geq 0$.

> *Case (1): If $\theta \in I_k$ for some integer k,*
> *then assume that $\partial\Omega$ is strictly $\overrightarrow{\mathbf{F}}_{\theta} = \mathbf{\Lambda}_k$-convex.*

> *Case (2): If $\theta = \theta_k$ is a special value,*
> *then assume that $\partial\Omega$ is strictly $\overrightarrow{\mathbf{F}}_{\theta_k} = \mathbf{\Lambda}_k^{\sigma_{n-1}}$-convex.*

Then Perron existence holds for $\mathbf{F}_{\theta}$ on Ω.

We remind the reader of the geometric characterizations of these boundary convexity hypotheses given in Theorem 2.1.

6. The Inhomogeneous Dirichlet Problem for the SL Potential Operator

We now consider the Dirichlet problem for $\text{tr}\{\arctan(D_x^2 u)\} = \psi(x)$.

Inhomogeneous equations of this sort were studied in [IDP] where the following was introduced. An operator f, such as $f(A) = \text{tr}\{\arctan A\}$, is said to be **tamable** on a subequation $\mathbf{F}$ if there exists $\chi : f(\mathbf{F}) \to \mathbb{R}$ strictly

increasing, such that $g(A) \equiv \chi(f(A))$ is **tame** on $\mathbf{F}$ where "tame" means that for all $t > 0$ there exists $c(t) > 0$ such that

$$g(A + tI) - g(A) \geq c(t) \qquad \forall A \in \mathbf{F}. \tag{6.1}$$

For tamable operators there are nice results for the Dirichlet problem [IDP].

The following result was inspired by the paper of Collins, Picard and Wu [CPW].

THEOREM 6.1. *If (and only if) the phase θ belongs to the highest phase interval $I_1 = ((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$, then the SL potential operator $f(A) = \mathrm{tr}\{\arctan A\}$ is tamable on $\mathbf{F}_\theta$. More specifically, $\tan\{\frac{1}{n} f(A)\}$ is tame on $f^{-1}\{[(n-2)\frac{\pi}{2} + \delta, n\frac{\pi}{2})\} \equiv \mathbf{F}_\theta$ where $\theta \equiv (n-2)\frac{\pi}{2} + \delta$ with $\delta > 0$. (The $\frac{1}{n}$ factor is a matter of convenience and not necessary here.)*

Note that $\overrightarrow{\mathbf{F}}_\theta = \mathcal{P}$ if $\theta \in I_1$ by Theorem 4.1, and hence the appropriate boundary convexity is just ordinary strict convexity. By Theorem 2.7′ in [IDP], Theorem 6.1 gives a different proof of Part A of the following.

THEOREM 6.2.

A. (S. Dinew, H.-S. Do and T. D. Tô [DDT]) *Suppose Ω is a bounded domain with smooth strictly convex boundary $\partial\Omega$. Then for any inhomogeneous term $\psi \in C(\overline{\Omega})$ with values $\psi(\overline{\Omega}) \subset ((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$ and any boundary function $\varphi \in C(\partial\Omega)$, there exists a unique solution $u \in C(\overline{\Omega})$ to*

$$\mathrm{tr}\left\{\arctan(D_x^2 u)\right\} = \psi(x) \quad \text{on} \quad \Omega \quad \text{with} \quad u\big|_{\partial\Omega} = \varphi. \tag{6.2}$$

B. (M. Cirant and K. Payne [CP, Thm. 6.18]) *Let $\Omega \subset\subset \mathbb{R}^n$ be a domain and consider an inhomogeneous term $\psi \in C(\overline{\Omega})$ with values in I_k, i.e.*

$$\psi(\overline{\Omega}) \subset I_k = \left((n-2k)\frac{\pi}{2}, (n-2(k-1))\frac{\pi}{2}\right)$$

for some k with $1 \leq k \leq n$. Then comparison holds for the subequation $\mathbf{F}_\psi \subset \Omega \times \mathrm{Sym}^2(\mathbb{R}^n)$ given by

$$\mathbf{F}_\psi \equiv \{(x, A) : \mathrm{tr}\{\arctan A\} \geq \psi(x)\}$$

C. *Let $\Omega \subset\subset \mathbb{R}^n$ be a domain with smooth boundary which is strictly $\min\{k, n-k+1\}$-convex (by Definition 2.2). Let $\psi \in C(\overline{\Omega})$ be as in Part B. Then there exists a unique solution $u \in C(\overline{\Omega})$ to the Dirichlet problem (6.2) for all continuous boundary values $\varphi \in C(\partial\Omega)$.*

Proof of Part C. This follows from Part B together with Theorem 13.3 in [DDR] and Theorem 2.1 above. ∎

Part C is the best known result on the inhomogeneous Dirichlet problem in the continuous case.

A smooth version of Part A was proved (prior to Theorem 6.2) in [CPW].

THEOREM 6.3. (Collins, Picard and Wu). *Suppose Ω is a bounded domain with smooth strictly convex C^4 boundary $\partial\Omega$. Consider an inhomogeneous term $\psi \in C^2(\overline{\Omega})$ with values $\psi(\overline{\Omega}) \subset I_1 \equiv ((n-2)\frac{\pi}{2}, n\frac{\pi}{2})$ and any boundary function $\varphi \in C^4(\partial\Omega)$. Suppose there exists a function $\underline{u} \in C^4(\overline{\Omega})$ which is a subsolution on Ω and satisfies $\underline{u} = \varphi$ on $\partial\Omega$. Then there exists a unique $C^{3,\alpha}(\overline{\Omega})$ solution u to the Dirichlet problem (6.2). If all data are C^∞, so is u.*

This problem has a nice geometric meaning, given in the following proposition. The result was stated in [CG; (2.19)], with proof left to the reader. Since this paper is solely concerned with the SL Potential equation, we have given a proof in Appendix A (See Proposition A.1 and Corollary A.2).

Proposition 6.4. *Let L be an Lagrangian submanifold of $\mathbb{R}^n \oplus \mathbb{R}^n \cong \mathbb{R}^n \oplus i\mathbb{R}^n = \mathbb{C}^n$. Assume L is a graph over a domain in $\mathbb{R}^n \oplus \{0\}$ and is oriented by $x_1, ..., x_n$. Set $dz \equiv dz_1 \wedge \cdots \wedge dz_n$. Then*

$$dz\big|_L = e^{i\theta} d\mathrm{vol}_L,$$

and

$$\nabla\theta = -JH$$

where H is the mean curvature vector of L, and J is the complex structure.

Corollary 6.5. *Let u be the solution of the inhomogeneous SL equation (5.2) which is C^2 on $X^{\mathrm{open}} \subset \mathbb{R}^n$. Let L be the graph of ∇u in $X \times \mathbb{R}^n$. Let $\widetilde{\psi}$ be the pull-back of ψ to L. Then*

$$\nabla\widetilde{\psi} = -JH.$$

Thus, a C^2 solution of (6.2) is giving a Lagrangian submanifold whose mean curvature vector H is

$$H = -J\nabla\widetilde{\psi} \qquad \mathrm{on} \quad L$$

Proof. The function θ is just $\mathrm{tr}\{\arctan D^2 u\}$ pulled back to L. ∎

This result was generalized by Micah Warren to a family of operators and associated Lagrangian graphs which he found in his thesis. For this see (6.7) in [Wa].

Open Question: It is unclear whether or not some version of Theorem 6.2 remains true for all possible inhomogeneous terms $\psi \in C(\overline{\Omega})$, i.e., ψ's taking values in (a compact subset of) the open interval $(-n\frac{\pi}{2}, n\frac{\pi}{2})$.

Proof of Theorem 6.1 Set $\delta \equiv \theta - (n-2)\frac{\pi}{2} > 0$. Adopt the notation $h'(A) \equiv \frac{d}{dt}h(A+tI)\big|_{t=0}$. Set

$$g(A) \equiv \chi(f(A)), \qquad \text{where } \chi(x) \equiv \tan\left(\frac{x}{n}\right).$$

It suffices to show that for some $c > 0$

$$g'(A) \geq c \qquad \forall A \in \mathbf{F}_\theta. \tag{6.3}$$

Let $\lambda_1 \leq \cdots \leq \lambda_n$ denote the ordered eigenvalues of A. Then $f(A) = \sum_{j=1}^n \arctan(\lambda_j)$, and hence

$$f'(A) = \sum_{j=1}^n \frac{1}{1+\lambda_j^2}. \tag{6.4}$$

Therefore we have

$$g'(A) = \chi'(f(A)) \sum_{j=1}^n \frac{1}{1+\lambda_j^2}. \tag{6.5}$$

Case 1: $A > 0$. Since $0 < \lambda_1 \leq \lambda_2 \leq \cdots \lambda_n$ we have $f(A) = \sum_j \arctan(\lambda_j) \geq n\arctan(\lambda_1) > 0$. Now

$$\chi'(x) = \frac{1}{n}\left(1+\tan^2\left(\frac{x}{n}\right)\right) = \frac{1}{n}\left(1+\chi^2(x)\right). \tag{6.6}$$

Moreover, $\chi'(x)$ is strictly increasing in x for $x \geq 0$. Hence,

$$\chi'(f(A)) \geq \chi'(n\arctan\lambda_1) = \frac{1}{n}\left(1+\tan^2(\arctan\lambda_1)\right) = \frac{1}{n}(1+\lambda_1^2).$$

Hence, we have

$$g'(A) = \chi'(f(A)) \sum_{j=1}^n \frac{1}{1+\lambda_j^2} \geq \frac{1}{n}(1+\lambda_1^2) \sum_{j=1}^n \frac{1}{1+\lambda_j^2} \geq \frac{1}{n}.$$

Case 2: $\lambda_1 \leq 0$. Suppose we can show that $\theta \in I_1$ implies that

$$-\tan\left(\frac{\pi}{2}-\delta\right) \leq \lambda_1(A). \tag{6.7}$$

Note that

$$f'(A) = \sum_{j=1}^n \frac{1}{1+\lambda_j^2} \geq \frac{1}{1+\lambda_1^2}.$$

Since $\lambda_1 \leq 0$, (6.7) implies that $\lambda_1^2 \leq \tan^2(\frac{\pi}{2}-\delta)$, and hence $1/(1+\lambda_1^2) \geq 1/(1+\tan^2(\frac{\pi}{2}-\delta))$. Therefore,

$$f'(A) \geq \frac{1}{1+\tan^2\left(\frac{\pi}{2}-\delta\right)}. \tag{6.8}$$

Note that by (6.6) we have $\chi'(x) \geq \frac{1}{n}$. Therefore,

$$g'(A) \;=\; \chi'(f(A))f'(A) \;\geq\; \frac{\frac{1}{n}}{1 + \tan^2\left(\frac{\pi}{2} - \delta\right)}.$$

In Case 1 the lower bound $\frac{1}{n}$ is larger than here. Therefore (6.3) follows with $c^{-1} \equiv n(1 + \tan^2(\frac{\pi}{2} - \delta))$ if we show (6.7). This is immediate from the following.

Lemma 6.6. *If $A \in \mathbf{F}_\theta$ and $(n-2)\frac{\pi}{2} < \theta < n\frac{\pi}{2}$, i.e., $\theta \in I_1$, then*

(1) *A must have at least $n-1$ strictly positive eigenvalues, and*

(2) *if A has a negative eigenvalue, then with $\delta \equiv \theta - (n-2)\frac{\pi}{2}$*

$$-\tan\left(\frac{\pi}{2} - \delta\right) \;<\; \lambda_1(A).$$

Proof of (1). Let $p(A) \equiv \#\{\lambda_j > 0\}$. Then

$$(n-2)\frac{\pi}{2} < \theta \leq \sum_{j=1}^n \arctan \lambda_j \leq \sum_{\lambda_j > 0} \arctan \lambda_j < p(A)\frac{\pi}{2}.$$

Hence, $n - 2 < p(A)$.   ∎

Proof of (2). Note that

$$(n-2)\frac{\pi}{2} + \delta \equiv \theta \leq \sum_{\lambda_j > 0} \arctan \lambda_j - \arctan(-\lambda_1) < (n-1)\frac{\pi}{2} - \arctan(-\lambda_1),$$

and hence $\arctan(-\lambda_1) < \frac{\pi}{2} - \delta$ so that $-\lambda_1 < \tan(\frac{\pi}{2} - \delta)$.   ∎

This complete the proof of the "if" part of Theorem 6.1.

Note: As an immediate consequence of Lemma 6.6, if θ belongs to the top phase interval I_1, then each $\mathbf{F}_\theta$-subharmonic function is quasi-convex, in fact $\tan(\frac{\pi}{2} - \delta)$-quasi-convex.

The "only if" part of Theorem 6.1 was proved in [IDP, Prop. 6.19]. We include the proof here for the reader's convenience.

Lemma 6.7. *The operator $f(A) \equiv \mathrm{tr}\{\arctan(A)\}$ is not tamable on $\mathbf{F}_\theta \equiv \{A : f(A) \geq \theta\}$ for $\theta \leq (n-2)\frac{\pi}{2}$.*

Proof. Consider A with $\lambda_1(A) << 0$ and $\lambda_k(A) >> 0$ for $k > 1$. We can always choose these values so that $f(A) = (n-2)\frac{\pi}{2}$. As the absolute value of the eigenvalues becomes very large the derivative of $f(A)$ goes to zero. Hence, no matter which smooth function χ one chooses, the composition $\chi \circ f$ will have derivatives going to zero at these points, since $\chi'(f(A))$ will not go to ∞ unless $f(A)$ goes to $\frac{n\pi}{2}$.   ∎

This completes the proof of Theorem 6.1.   ∎

7. A Generalized Version of the Main Theorem 4.1.

The main results in this paper hold with the eigenvalues of A replaced by the Gårding eigenvalues of A. We refer to the introduction for definitions and statements. Let $\mathfrak{g}$ be a Gårding-Dirichlet polynomial of degree m with ordered Gårding eigenvalues $\lambda_k^{\mathfrak{g}}$ and associated branches $\mathbf{\Lambda}_k^{\mathfrak{g}} \equiv \{\lambda_k^{\mathfrak{g}} \geq 0\}$, for $k = 1, ..., m$. One has

$$\mathfrak{g}(tI + A) \;=\; \mathfrak{g}(I) \prod_{k=1}^{m} (t + \lambda_k^{\mathfrak{g}}(A)) \;=\; \mathfrak{g}(I)\left(t^m + \sigma_1^{\mathfrak{g}}(A)t^{m-1} + \cdots + \sigma_m^{\mathfrak{g}}(A)\right).$$

The derivative $\mathfrak{g}'(A) \equiv \frac{1}{m}\frac{d}{dt}\mathfrak{g}(tI + A)\big|_{t=0}$. is a Gårding-Dirichlet polynomial of degree $m - 1$ whose eigenvalues $\lambda_k^{\mathfrak{g}'}$ are the critical points of $\mathfrak{g}(tI + A)$. Note that

$$\sigma_m(A) \;=\; \mathfrak{g}(A) \qquad \text{and} \qquad \sigma_{m-1}^{\mathfrak{g}}(A) \;=\; \mathfrak{g}'(A). \tag{7.1}$$

We begin by looking at the asymptotic expansion of the $\mathfrak{g}$-SL potential operator.

Lemma 7.1. *Suppose $\mathfrak{g}(A) \neq 0$. Then*

$$f^{\mathfrak{g}}(tA) \;\equiv\; \sum_{k=1}^{m} \arctan \lambda_k^{\mathfrak{g}}(tA)$$

$$= (m - 2q(A))\frac{\pi}{2} \;-\; \frac{1}{t}\frac{\mathfrak{g}'(A)}{\mathfrak{g}(A)} \;+\; O\left(\frac{1}{t^3}\right) \qquad \text{as } t \to \infty.$$

where $q(A)$ now denotes the number of strictly negative $\mathfrak{g}$-eigenvalues of A.

Proof. Note from the first display above that $\lambda_k^{\mathfrak{g}}(tA) = t\lambda_k^{\mathfrak{g}}(A)$ and so $f^{\mathfrak{g}}(tA) = \sum_{k=1}^{m} \arctan(t\,\lambda_k^{\mathfrak{g}}(A))$. Since $\mathfrak{g}(A) = \lambda_1^{\mathfrak{g}}(A)\cdots\lambda_m^{\mathfrak{g}}(A) \neq 0$, all the eigenvalues are non-zero, and so the difference between the number of strictly positive eigenvalues and the number of strictly negative ones is $(m - q(A)) - q(A) = m - 2q(A)$. The proof is now the same as that of Lemma 4.2. ∎

Corollary 7.2. *Suppose $\mathfrak{g}(A) \neq 0$. Then Corollary 4.3 holds with $f(tA)$ replaced by $f^{\mathfrak{g}}(tA)$.*

Now Generalized Theorem 4.1 can be rephrased as Generalized Theorem 4.1$'$ exactly as Theorem 4.1 was rephrased as Theorem 4.1$'$. Also the analogue of Lemma 4.4 holds here.

The next step is to generalize Proposition 4.5. Here the statement and arguments are essentially identical to those in Section 4. We state the part concerning the interior, since that is what is important for the Dirichlet problem

Proposition 7.3. *For $k = 1, ..., m$, the set* $\text{Int}\mathbf{\Lambda}_k^{\sigma_{m-1}^{\mathfrak{g}}}$ *is a disjoint union* $\text{Int}\mathbf{\Lambda}_k^{\sigma_{m-1}^{\mathfrak{g}}} = (\text{Int}\mathbf{\Lambda}_{k+1}^{\mathfrak{g}} \cap \mathbf{\Lambda}_k^{\mathfrak{g}}) \cup E_k$ *where*

$$E_k \equiv (\text{Int}\mathbf{\Lambda}_{k+1}^{\mathfrak{g}} \sim \mathbf{\Lambda}_k^{\mathfrak{g}}) \cap \{\sigma_{m-1}^{\mathfrak{g}}(A)\,\sigma_m^{\mathfrak{g}}(A)\ < 0\}.$$

The remainder of the proof of Generalized Theorem 4.1′ follows exactly the argument given for the "Proof of Theorem 4.1′ (2)′" in Section 4. ∎

The SL Curvature Operator
for the Second Fundamental Form of the Graph

Here we include some brief remarks on another way to diversify the SL operator by looking at the second fundamental form of the graph of a scalar function u. For this operator very little is known concerning uniqueness (for the (DP)). However, our result establishing the appropriate strict boundary convexity carries over and provides existence for the broad class of appropriately "pseudo-convex" domains.

Definition 7.4. (The SL-Curvature Operator). Given a smooth function u on an open subset $X \subset \mathbb{R}^n$, let $\kappa_1(x), ..., \kappa_n(x)$ denote the principal curvatures of it graph $M \subset \mathbb{R}^{n+1}$. Replacing the eigenvalues of $D_x^2 u$ in (1.1), by these principal curvatures, yields the **SL-curvature operator** SL^{curv} defined by (7.2) below.

This operator was first studied by Graham Smith. In [GS1] he restricts to functions u with $D^2 u > 0$ and $\theta \in [(n-1)\frac{\pi}{2}, n\frac{\pi}{2})$, and he looks at the number ρ such that $\sum_j \arctan\{\rho\kappa_j\} = \theta$. When $\theta = (n-1)\frac{\pi}{2}$, he gives a very nice geometric interpretation of this "curvature" ρ (see (i)–(iii) on page 59 of [GS1]).

As noted in [DDR, Sec. 11.5], using jet variables $p = D_x u$ and $A = D_x^2 u$, if we define

$$E_p = P_{p^\perp} + \frac{1}{\sqrt{1+|p|^2}}P_p = I - \frac{|p|^2}{\sqrt{1+|p|^2}(1+\sqrt{1+|p|^2})}P_p, \quad (7.1)$$

then

$$II(u) \equiv \frac{1}{\sqrt{1+|p|^2}}E_p A E_p$$

is the second fundamental form of the graph M of u, so that its eigenvalues are the principal curvatures $\kappa_1, ..., \kappa_n$ of M. Thus

$$SL^{\text{curv}}(p, A) \equiv \text{tr}\{\arctan II(u)\} = \sum_{j=1}^n \arctan \kappa_j. \quad (7.2)$$

For phases θ in the allowable range $-n\frac{\pi}{2} < \theta < n\frac{\pi}{2}$,

$$\mathcal{F}_\theta \equiv \{(p, A) : SL^{\mathrm{curv}}(p, A) \geq \theta\} \tag{7.3}$$

is a subequation, which is constant coefficient and reduced, but **not** pure second order. The positivity requirement, that $SL^{\mathrm{curv}}(A + P) \geq SL^{\mathrm{curv}}(A)$ for $P \geq 0$, follows from the fact that $\langle E_p P E_p x, x \rangle = \langle P(E_p x), E_p x \rangle$ so that $P \geq 0 \Rightarrow E_p P E_p \geq 0$.

In fact for each fixed $p \in \mathbb{R}^n$,

$$g(A) \equiv \det\left(\frac{1}{\sqrt{1 + |p|^2}} E_p A E_p\right) = \det(II(u)) \tag{7.4}$$

is a Gårding/Dirichlet polynomial in A whose eigenvalues (the negatives of the roots of $\det(tI + E_p A E_p)$) are the curvatures $\kappa_1(p, A), ..., \kappa_n(p, A)$. In particular, $\mathcal{F}_\theta$ fibres over $\mathbb{R}^n$, with fibre at p given by the pure second-order subequation

$$(\mathcal{F}_\theta)_p = \frac{1}{1 + |p|^2} E_p \mathbf{F}_\theta E_p, \quad \text{i.e.}$$

$$(p, A) \in \mathcal{F}_\theta \quad \Longleftrightarrow \quad B \equiv (1 + |p|^2) E_p^{-1} A E_p^{-1} \in \mathbf{F}_\theta. \tag{7.5}$$

In addition, the fibres of the interior are the interiors of the fibres. Consequently, the asymptotic interior $\overrightarrow{\mathrm{Int}}\mathcal{F}_\theta$ can be computed fibrewise with the answer given by Theorem 4.1$'$. This gives the following optimal pseudoconvexity result for the SL curvature operator. The proof is left to the reader.

Theorem 4.1$'$ for the SL Curvature Operator. Let $\mathcal{L}_k$ be the set where the kth ordered eigenvalue $\kappa_k(p, A)$ is ≥ 0. Let $\mathcal{L}_k^{\sigma_{n-1}}$ also be defined in analogy with section 3.

$(1)'$ If $\theta \in I_k$ $(k = 1, ..., n)$, then

$$\overrightarrow{\mathrm{Int}}\mathcal{F}_\theta = \mathrm{Int}\mathcal{L}_k.$$

$(2)'$ If θ_k $(k = 1, ..., n - 1)$ is a special value, then

$$\overrightarrow{\mathrm{Int}}\,\mathcal{F}_{\theta_k} = \mathrm{Int}\mathcal{L}_k^{\sigma_{n-1}}.$$

Given $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$, consider the (DP) for $\mathcal{F}_\theta$ on a domain $\Omega \subset\subset \mathbb{R}^n$ with general boundary function $\varphi \in C(\partial\Omega)$. None of the available comparison techniques seem to apply. Thus:

Comparison for $\mathcal{F}_\theta$ remains an interesting open question. $\tag{7.6}$

What we do know from [DDR] can be outlined as follows. From Definition 8.2 and Theorem 10.1 in [DDR] we have:

A weak form of comparison holds. $\tag{7.7}$

Assume that $\partial\Omega$ is smooth and strictly $\mathcal{F}_{|\theta|}$-convex. Then from Theorem 13.4 in [DDR]:

$$\text{Existence holds for the } \mathcal{F}_\theta \text{ (DP) on } \Omega \text{ for all } \varphi \in C(\partial\Omega), \qquad (7.8)$$

and from Theorem 12.7 in [DDR]:

$$\text{All solutions for the } \mathcal{F}_\theta \text{ (DP) on } \Omega \text{ for } \varphi \in C(\partial\Omega).$$
are squeezed between a maximal solution and a minimal solution, $\quad$ (7.9)
namely the two Perron solutions.

Remark 7.5. (Radial Harmonics). Suppose $u(x) \equiv \psi(|x|)$, $r \equiv |x|$ is a radial solution to $SL^{\mathrm{curv}}(D_x u, D_x^2 u) = \theta$. Then $p = D_x u = \psi'(r)\frac{x}{r}$ and $A = D_x^2 u = \frac{\psi'(r)}{r}P_{x^\perp} + \psi''(r)P_x$. Note that A commutes with E_p. Set $y(r) \equiv \psi'(r)$. One computes that

$$\frac{1}{\sqrt{1+|p|^2}}E_p A E_p \;=\; \frac{1}{\sqrt{1+y^2}}\frac{y}{r}P_{x^\perp} + \frac{y'}{(1+y^2)^{\frac{3}{2}}}P_x. \qquad (7.10)$$

Hence the principal curvatures of the graph of $\psi(|x|)$ are:

$$\frac{1}{r}\frac{y}{\sqrt{1+y^2}} \quad \text{with multiplicity } n-1 \text{ and } \quad \frac{y'}{(1+y^2)^{\frac{3}{2}}} \quad \text{with multiplicity 1.}$$

It follows that:

$$\begin{aligned}
0 \;=\; & \mathrm{Im}\left(e^{-i\theta}\left(1 + i\frac{y}{r\sqrt{1+y^2}}\right)^{n-1}\left(1 + i\frac{y'}{(1+y^2)^{\frac{3}{2}}}\right)\right) \\
\;=\; & \frac{1}{nr^{n-1}}\frac{d}{dr}\mathrm{Im}\left(e^{-i\theta}\left(r + i\frac{y}{\sqrt{1+y^2}}\right)^n\right)
\end{aligned} \qquad (7.11)$$

since $\frac{d}{dr}\frac{y}{\sqrt{1+y^2}} = \frac{y'}{(1+y^2)^{\frac{3}{2}}}$.

This proves that $SL^{\mathrm{curv}}(D_x u, D_x^2 u) = \theta$ implies

$$\mathrm{Im}\left(e^{-i\theta}\left(r + i\frac{y}{\sqrt{1+y^2}}\right)^n\right) \;=\; c \qquad \text{a constant.} \qquad (7.12)$$

Compare this with the calculation in [CG] pp. 99-100 that if $SL(D_x^2 u) = \theta$, then $\mathrm{Im}(r + iy)^n = c$, a constant.

We leave it to the reader to calculate some low dimensional cases.

8. Results on Riemannian Manifolds.

Via the work in [DDR] the results above can be carried over to fairly general spaces. Let $\Omega \subset\subset X$ be a domain with smooth boundary in a riemannian n-manifold, and let $\operatorname{Hess} u \in C^\infty(\operatorname{Sym}^2(T^*(X)))$ be the riemannian Hessian. Then for C^2-functions u the SL potential operator

$$f(\operatorname{Hess} u) \;=\; \operatorname{tr}\{\arctan(\operatorname{Hess} u)\}$$

makes sense and extends to upper semi-continuous functions. For $\theta \in (-n\frac{\pi}{2}, n\frac{\pi}{2})$ we have the subequation $\mathbf{F}_\theta$ on X and the associated equation $\partial\mathbf{F}_\theta$. These equations are locally jet-equivalent to the constant coefficient equations discussed above, and so the work in [DDR] applies.

The strict boundary convexity assumption on the second fundamental form, analyzed in Section 4, carries over directly to $\partial\Omega$. We assume this is satisfied, and that there exists a smooth convex function defined on X.

THEOREM 8.1. [DDR]. *For each $\varphi \in C(\partial\Omega)$ there exists a unique solution $u \in C(\overline{\Omega})$ to the Dirichlet problem, i.e., u is an $\mathbf{F}_\theta$-harmonic function on Ω and $u\big|_{\partial\Omega} = \varphi$.*

This extends more generally as follows. Let X be a riemannian n-manifold with a topological G-structure for a compact group $G \subset \mathrm{O}(n)$. Let $\mathfrak{g}$ be a G-invariant Gårding-Dirichlet polynomial of degree m on $\operatorname{Sym}^2(\mathbb{R}^n)$. Then we have a well defined SL potential operator

$$f^{\mathfrak{g}}(\operatorname{Hess} u) \;=\; \sum_{k=1}^{m} \arctan\{\lambda_k^{\mathfrak{g}}(\operatorname{Hess} u)\}$$

where $\lambda_k^{\mathfrak{g}}(A)$ are the Gårding eigenvalues of A. We have the subequation $\mathbf{F}_\theta^{\mathfrak{g}}$ for $\theta \in (-m\frac{\pi}{2}, m\frac{\pi}{2})$ and its associated equation. We suppose that X carries a smooth strictly Γ-subharmonic function where Γ is the Gårding cone for $\mathfrak{g}$.

THEOREM 8.2. *Suppose that $\partial\Omega$ satisfies the strict boundary convexity hypothesis for $\mathbf{F}_\theta^{\mathfrak{g}}$. Then for each $\varphi \in C(\partial\Omega)$ there exists a unique solution $u \in C(\overline{\Omega})$ to the Dirichlet problem, i.e., u is an $\mathbf{F}_\theta^{\mathfrak{g}}$-harmonic function on Ω and $u\big|_{\partial\Omega} = \varphi$.*

Example 8.3. Suppose (X, J) is an almost complex riemannnian manifold where J is orthogonal. Then we can take $\mathfrak{g}(A) = \det_{\mathbb{C}}(A_{\mathbb{C}})$ where $A_{\mathbb{C}} \equiv \frac{1}{2}(A - JAJ)$. Here the Γ-subharmonic functions are exactly the plurisubharmonic functions. This gives solutions to the complex SL potential equation. There is a quaternionic analogue. One also has in the complex case the Lagrangian Monge-Ampère operator discussed in [Lag].

Appendix A. A Geometric Interpretation of the Inhomogeneous DP.

The equation (A.1) below appeared as equation (2.18) in [CG]. We left the proof as a exercise for the reader. However, this equation has an immediate consequence for the Dirichlet problem for the inhomogeneous SL equation (A.2), which is discussed in Section 5. This is given in Corollary A.2. It may have gone unnoticed and seems not to be well understood. For the convenience of the reader we give the proof of equation (2.18) in [CG] here.

Proposition A.1. *Let X be a Calabi-Yau manifold of complex dimension n. Let Φ be the parallel $(n, 0)$-form normalized so that $\mathrm{Re}\Phi$ has comass 1. Given $L \subset X$ an oriented Lagrangian submanifold, define the phase θ mod 2π by*

$$\Phi\big|_L \;=\; e^{i\theta} d\mathrm{vol}_L.$$

Then for any tangent vector field V on L, we have

$$V\theta \;=\; \langle JV, H \rangle,$$

that is

$$\nabla\theta \;=\; -JH \qquad\qquad\qquad (A.1)$$

where H is the mean-curvature vector field of L, and J is the complex structure on X.

Proposition A.1 has the following immediate implication for the inhomogeneous SL potential equation $\mathrm{tr}\left\{\arctan(D_x^2 u)\right\} \;=\; \psi(x)$. Let $z \equiv x + iy \in \mathbb{R}^n \oplus i\mathbb{R}^n = \mathbb{C}^n$

Corollary A.2. *Suppose $L \equiv \{(x, \nabla u(x)) : x \in \Omega\}$ is the graph of the gradient of $u \in C^2(\Omega)$ over a domain $\Omega \subset \mathbb{R}^n$. Then the inhomogeneous term*

$$\theta(x) \;\equiv\; \mathrm{tr}\left\{\arctan D_x^2 u\right\}, \qquad\qquad (A.2)$$

considered as a function on L, is the phase function for L. Thus it has gradient related to the mean curvature vector field H of L by

$$\nabla\theta \;=\; -JH \qquad \text{on } L. \qquad\qquad (A.3)$$

Otherwise said, if u is a solution to the equation

$$\mathrm{tr}\left\{\arctan(D_x^2 u)\right\} \;=\; \psi(x)$$

on Ω, with $\psi(x)$ smooth, then

$$\nabla\widetilde{\psi} \;=\; -JH \qquad \text{on } \; L \qquad\qquad (A.3)$$

where $\widetilde{\psi}$ is the pull-back of ψ to L.

Note. Proposition A.1 is actually independent of the orientation of L. A change of orientation changes the function θ to $\theta + \pi$, and the conclusion is the same. In Corollary A.2, L is given the orientation of Ω.

Proof of Proposition A.1. By a complex linear change of coordinates we may assume at p we have $\Phi = dz_1 \wedge \cdots \wedge dz_n$. Now let $p = (x_0, \nabla u(x_0))$. The map $D^2 u$ is symmetric, so by a change of variables $(x, y) \to (gx, gy)$ for some

$g \in \mathrm{SO}(n)$, we can assume that at x_0, $D^2 u$ is diagonal, i.e., $(D^2_{x_0} u)(\epsilon_k) = \lambda_k \epsilon_k$ for an orthonormal basis $\epsilon_1, ..., \epsilon_n$ of $\mathbb{R}^n$.

Now let $e_1, ..., e_n$ be an oriented orthonormal frame field on L in a neighborhood of $p = (x_0, \nabla u(x_0))$. Then

$$\Phi(e_1 \wedge \cdots \wedge e_n) \;=\; e^{i\theta},$$

and so

$$V e^{i\theta} \;=\; e^{i\theta} i V \theta \;=\; \Phi\left(\sum_{k=1}^{n} e_1 \wedge \cdots \wedge (\nabla_V e_k) \wedge \cdots \wedge e_n\right)$$

since Φ is parallel. We may assume $\nabla^L_{e_j} e_k = (\nabla_{e_j} e_k)^{\mathrm{tang}} = 0$ at x_0, so $\nabla_V e_k = (\nabla_V e_k)^{\mathrm{normal}} = B_{V,e_k}$ the second fundamental form of L at x_0. Therefore we have

$$V e^{i\theta} \;=\; e^{i\theta} i V \theta \;=\; \Phi\left(\sum_{k=1}^{n} e_1 \wedge \cdots \wedge B_{V,e_k} \wedge \cdots \wedge e_n\right),$$

and we can write

$$B_{V,e_k} \;=\; \sum_{j=1}^{n} \langle B_{V,e_k}, J e_j \rangle J e_j.$$

Now pick the frame field at x_0 to be

$$e_k = \frac{1}{\sqrt{1 + \lambda_k^2}} (\epsilon_k + \lambda_k J \epsilon_k), \qquad \text{for} \quad k = 1, ..., n,$$

so that at x_0 the vectors e_k and $J e_k$ lie in the kth complex coordinate line. Recall that at the point p, $\Phi = dz_1 \wedge \cdots \wedge dz_n$. Hence, at p

$$V e^{i\theta} \;=\; e^{i\theta} i V\theta = \{dz\}\left(\sum_{k=1}^{n} e_1 \wedge \cdots \wedge B_{V,e_k} \wedge \cdots \wedge e_n\right)$$

$$= \sum_k dz_1(e_1) \cdots dz_k \left(\sum_j \langle B_{V,e_k}, J e_j \rangle J e_j\right) \cdots dz_n(e_n)$$

$$= \sum_k dz_1(e_1) \cdots dz_k \left(\langle B_{V,e_k}, J e_k \rangle J e_k\right) \cdots dz_n(e_n)$$

$$\equiv \sum_k dz_1(e_1) \cdots dz_k \left(\alpha_k J e_k\right) \cdots dz_n(e_n) \qquad \text{with} \quad \alpha_k \equiv \langle B_{V,e_k}, J e_j \rangle$$

$$= \sum_k dz_1(e_1) \cdots i \alpha_k dz_k (e_k) \cdots dz_n(e_n)$$

$$= i \sum_k \alpha_k dz(e_1 \wedge \cdots \wedge e_n) \;=\; i \left(\sum_k \alpha_k\right) e^{i\theta}.$$

Hence, with summation convention,

$$
\begin{aligned}
V\theta \;&=\; \sum_k \alpha_k \;=\; \langle B_{V,e_k}, Je_k \rangle \;=\; \langle \nabla_{e_k} V, Je_k \rangle \\
&=\; -\langle V, \nabla_{e_k} Je_k \rangle \;=\; -\langle V, J\nabla_{e_k} e_k \rangle \;=\; \langle JV, B_{e_k,e_k} \rangle \\
&=\; \langle JV, H \rangle.
\end{aligned}
$$

■

Appendix B. Remarks Concerning Convexity

Part of the point of this appendix is to show that strict $\overrightarrow{\mathbf{F}}_\theta$-convexity of the boundary $\partial\Omega$ is the right, i.e., borderline condition for the Dirichlet problem. This goes back to work in [CNS] for θ in the highest interval. We also discuss how this convexity relates to convexity of the domain Ω.

Let

$\Omega \subset\subset \mathbb{R}^n$ be a domain with smooth boundary $\partial\Omega$,

$\mathbf{F} \subset \mathrm{Sym}^2(\mathbb{R}^n)$ be a subequation,

$\lambda > 0$ be such that $(-\mathcal{P}) \cap (\lambda I + \mathbf{F}) = \emptyset$ (this always exists), and

$\varphi = -\frac{\lambda}{2}\|x\|^2\big|_{\partial\Omega}$.

Definition B.1. Ω is said to be $\mathbf{F}(\Omega)$-**convex** if for every $K \subset\subset \Omega$, one has $\widehat{K}^{\mathbf{F}(\Omega)} \subset\subset \Omega$ where $\widehat{K}^{\mathbf{F}(\Omega)} \overset{\text{def}}{=} \{x \in \Omega : f(x) \leq \sup_K f, \ \forall f \in \mathbf{F}(\Omega)\}$

Theorem B.2. *Assume there exists a function $h \in C^2(\overline{\Omega})$ such that*

   (i) $h\big|_\Omega \in \mathbf{F}(\Omega)$,

   (ii) $h\big|_{\partial\Omega} = \varphi$.

Then the domain Ω is $\mathbf{F}$-convex.

Furthermore, let $h^\star \overset{\text{def}}{=} h + \frac{\lambda}{2}\|x\|^2$. Then for every $x \in \partial\Omega$ where $(Dh^\star)_x \neq 0$, there exits $A \in (\lambda I + \mathbf{F})$ such that

$$
A\big|_{T_x(\partial\Omega)} \;=\; c_x B_x \tag{B.1}
$$

where $c_x > 0$ and B_x is the second fundamental form of $\partial\Omega$ at x with respect to the interior normal.

In particular, if $\mathbf{F} = \overrightarrow{\mathbb{G}}$ for a subequation $\mathbb{G}$, then $\partial\Omega$ is strictly $\mathbb{G}$-convex.

Proof. We begin by proving the second assertion. Fix $p \in \partial\Omega$ and w.l.o.g. assume p is the origin. Choose coordinates $x = (x', x_n)$ such that in a neighborhood of 0

$$
\Omega \;=\; \{(x', x_n) : x_n \geq g(x')\}
$$

where g is C^∞ with

$$g(0) \ = \ 0, \qquad (Dg)_0 = 0, \qquad \text{and} \qquad (D^2 g)_0 \ = \ B$$

where $B \overset{\text{def}}{=}$ the second fundamental form of $\partial\Omega$ at 0 w.r.t. the interior normal.

In a neighborhood U of we have a defining function for Ω given by

$$\rho(x) \ \equiv \ g(x') - x_n \tag{1}$$

with

$$(D^2\rho)_0 \ \equiv \ B.$$

Lemma B.3. *If $\widetilde\rho$ is any other defining function for Ω in U, then*

$$(D^2\widetilde\rho)\big|_{T_0(\partial\Omega)} \ \equiv \ |D\widetilde\rho|_0 B$$

Proof. In a neighborhood of 0 we have that $\widetilde\rho(x) = a(x)\rho(x)$ where $a > 0$. Now

$$D\widetilde\rho \ = \ (Da)\rho + a(D\rho)$$
$$D^2\widetilde\rho \ = \ (D^2 a)\rho + (Da)\circ(D\rho) + a(D^2\rho).$$

At $x = 0$ we have $\rho(0) = 0$ and $(D\rho)_0 = (0, ..., 0, -1) \equiv n$. Therefore,

$$(D\widetilde\rho)_0 \ = \ (0, ..., 0, -a(0))$$

$$(D^2\widetilde\rho)_0 \ = \ (Da \circ n) + a(0)(D^2\rho)_0 \qquad \text{and so}$$
$$(D^2\widetilde\rho)\big|_{T_0(\partial\Omega)} \ = \ a(0)(D^2\rho)\big|_{T_0(\partial\Omega)} \ = \ a(0)B. \qquad \blacksquare$$

Now $\varphi = -\frac{\lambda}{2}\|x\|^2\big|_{\partial\Omega}$, and $h \in C^2(\overline\Omega)$ is $\mathbf{F}$-subharmonic on Ω with boundary values φ. That is,

(1) $D^2 h \ \in \ \mathbf{F}$ on $\overline\Omega$,

(2) $(h - \varphi)\big|_{\partial\Omega} \ = \ 0.$

Recall that $h^\star \ \equiv \ h + \frac{\lambda}{2}\|x\|^2$ Note that $h^\star \in C^2(\overline\Omega)$ is an $\mathbf{F}^\star$-subharmonic function for the subequation

$$\mathbf{F}^\star \ \overset{\text{def}}{=} \ \lambda I + \mathbf{F}$$

with

$$h^\star\big|_{\partial\Omega} \ = \ 0.$$

Note also that $D^2 h^\star \ \in \ \lambda I + \mathbf{F} \ \subset \ \text{Int}\mathbf{F}$ by the positivity condition. Hence, $h^\star$ is strictly $\mathbf{F}$-subharmonic.

With the supposition that $(Dh^\star)_x \ne 0$. we have that $h^\star$ is a defining function for $\partial\Omega$ in a neighborhood of x. We now apply Lemma B.3 to establish the second assertion.

Now for the first assertion. By the definition of λ and Theorem 3.1 in [SMP] we know that $h^\star$ satisfies the Strong Maximum Principle, and so

$h^\star < 0$ on Ω. Suppose $K \subset\subset \Omega$ and let $\delta \equiv \mathrm{dist}(K, \partial\Omega) < 0$. Then we have $\widehat{K}^{\mathbf{F}(\Omega)} \subset \Omega_\delta \overset{\mathrm{def}}{=} \{x \in \Omega : h^\star(x) \leq \delta\}$. ∎
