
EXAM

Practice Midterm 2

Math 132

March 27, 2004

ANSWERS

Problem 1. Let $f(x) = \frac{e^x + e^{-x}}{2}$.

(a) Find the average value of f on the interval $[-1, 1]$.

Answer:

The average value of f on $[a, b]$ is $\frac{1}{b-a} \int_a^b f(x) dx$.

$$\frac{1}{2} \int_{-1}^1 \frac{e^x + e^{-x}}{2} dx = \frac{1}{2} \left(\frac{e^x - e^{-x}}{2} \right) \Big|_{-1}^1 = \frac{1}{2} \left(e - \frac{1}{e} \right) = 1.752 \dots$$

(b) Find the length of $y = f(x)$ from $x = -1$ to $x = 1$.

Answer:

$$\begin{aligned} L &= \int_{-1}^1 \sqrt{\left(\frac{dy}{dx}\right)^2 + 1} dx = \int_{-1}^1 \sqrt{\left(\frac{e^x - e^{-x}}{2}\right)^2 + 1} dx \\ &= \int_{-1}^1 \sqrt{\frac{e^{2x} - 2 + e^{-2x}}{4} + 1} dx \\ &= \int_{-1}^1 \sqrt{\frac{e^{2x} + 2 + e^{-2x}}{4}} dx \\ &= \int_{-1}^1 \sqrt{\left(\frac{e^x + e^{-x}}{2}\right)^2} dx \\ &= \int_{-1}^1 \frac{e^x + e^{-x}}{2} dx \\ &= \left. \frac{e^x - e^{-x}}{2} \right|_{-1}^1 \\ &= e - \frac{1}{e} = 2.350 \dots \end{aligned}$$

Problem 2. Solve the differential equation

$$y' = \frac{y \cos x}{1 + y^2}$$

subject to the initial condition $y(0) = 1$.

Answer:

$$\frac{dy}{dx} = \frac{y \cos(x)}{1 + y^2} \Rightarrow \frac{1 + y^2}{y} dy = \cos(x) dx \Rightarrow \int \frac{1}{y} + y dy = \int \cos(x) dx \Rightarrow \ln(y) + \frac{1}{2}y^2 = \sin(x) + C$$

The condition that $y(0) = 1$ means that C satisfies

$$\ln(1) + \frac{1}{2}1^2 = \sin(0) + C \Rightarrow \frac{1}{2} = C.$$

So, we have y satisfies the equation

$$\ln(y) + \frac{1}{2}y^2 = \sin(x) + \frac{1}{2}.$$

Problem 3. Sketch the solution curves to the differential equation $y' = -\frac{x}{y}$.

Answer:

We have

$$\frac{dy}{dx} = -\frac{x}{y} \Rightarrow y dy = -x dx \Rightarrow \frac{y^2}{2} = -\frac{x^2}{2} + C \Rightarrow x^2 + y^2 = 2C.$$

So, the solution curves are all circles centered at the origin.

Problem 4. True or False?

- (a) If y is any solution to $y' = x^4 + y^4 + y^2(1 - x)$, then y is increasing when $x < 1$.

Answer:

True, since $y' > 0$ when $x < 1$.

- (b) If W is the solution to the differential equation $\frac{dW}{dt} = \frac{3}{1000}W$ satisfying the initial condition $W(0) = 100$, then $W\left(\frac{1000}{3}\ln(5)\right) = 500$.

Answer:

True. You can see that from $\frac{dW}{dt} = \frac{3}{1000}W$ and $W(0) = 100 \Rightarrow W(t) = 100e^{\frac{3}{1000}t}$.

- (c) If W is the solution to the differential equation $\frac{dW}{dt} = \frac{3}{1000}W\left(1 - \frac{W}{400}\right)$ satisfying the initial condition $W(0) = 100$, then $\lim_{t \rightarrow \infty} W(t) = 400$.

Answer:

True. Here W satisfies the logistic equation with a max population of 400.

- (d) If C is one solution curve for the differential equation $y' = \frac{x^3 + 2x - e^x}{1 + e^x}$, then infinitely many other solution curves can be obtained by shifting C to the right or left.

Answer:

False. Here, y' depends on x so the solution curves through (x_1, y) and (x_2, y) for different x_1 and x_2 will definitely have a different shape. Note, however, that y' doesn't depend on y here, so the solutions will have the form $y = f(x) + K$ and all solutions will be obtained by *vertical* translation of any one particular solution curve.

- (e) If C is one solution curve for the differential equation $y' = \frac{y^3 + 2y - e^y}{1 + e^y}$, then infinitely many other solution curves can be obtained by shifting C to the right or left.

Answer:

True. This is because y' does not depend on x .

Problem 5. Consider the system of differential equations governing the population of aphids and ladybugs:

$$\begin{aligned}\frac{dA}{dt} &= 2A \left(1 - \frac{1}{10000}A\right) - \frac{1}{100}AL \\ \frac{dL}{dt} &= -\frac{1}{2}L + \frac{1}{10000}AL\end{aligned}$$

- (a) Describe what will happen to the population of aphids in the absence of ladybugs.

Answer:

(Note that this prob

Here, in the absence of ladybugs, A satisfies the logistic equation $\frac{dA}{dt} = 2A \left(1 - \frac{1}{10000}A\right)$ and one can see that $\lim_{t \rightarrow \infty} A(t) = 10000$.

- (b) Find the equilibrium solution of the system.

Answer:

There are three solutions to the equations

$$\begin{aligned}0 &= 2A \left(1 - \frac{1}{10000}A\right) - \frac{1}{100}AL \\ 0 &= -\frac{1}{2}L + \frac{1}{10000}AL\end{aligned}$$

We have $(A, L) = (0, 0)$, $(A, L) = (1000, 0)$, and $(A, L) = (5000, 100)$.

- (c) Find an expression for $\frac{dL}{dA}$.

Answer:

From the chain rule: $\frac{dL}{dA} = \frac{\frac{dL}{dt}}{\frac{dA}{dt}}$. So,

$$\frac{dL}{dA} = \frac{-\frac{1}{2}L + \frac{1}{10000}AL}{2A \left(1 - \frac{1}{10000}A\right) - \frac{1}{100}AL}$$

Problem 6. Use Euler's method with step size 0.2 to approximate $y(0.4)$ where $y(x)$ is the solution to the differential equation $y' = 2xy^2$ with the initial value $y(0) = 1$.

Answer:

Here, we have

$$(x_0, y_0) = (0, 1) \Rightarrow y'_0 = 2x_0y_0^2 = 0 \Rightarrow y_1 = y_0 + (0.2)y'_0 = 1 + 0 = 1$$

$$(x_1, y_1) = (0.2, 1) \Rightarrow y'_1 = 2x_1y_1^2 = 0.4 \Rightarrow y_2 = y_1 + (0.2)y'_1 = 1 + (0.2)(0.4) = 1.08$$

$$(x_2, y_2) = (0.4, 1.08).$$

Problem 7. Find a formula for the general term a_n of the sequence assuming that the general pattern of the first few terms continues:

(a) $\{1, 6, 11, 16, \dots\}$

Answer:

$$a_n = 5n - 4$$

(b) $\left\{-\frac{3}{4}, \frac{9}{16}, -\frac{27}{64}, \dots\right\}$

Answer:

$$a_n \left(-\frac{3}{4}\right)^n$$

Problem 8. Does the series $\sum_{n=1}^{\infty} \frac{n}{2n+1}$ converge or diverge? Explain.

Answer:

This series $\sum_{n=1}^{\infty} \frac{n}{2n+1} = \frac{1}{3} + \frac{2}{5} + \frac{3}{7} + \frac{4}{9} + \dots$ diverges. Note that

$$\lim_{n \rightarrow \infty} \frac{n}{2n+1} = \frac{1}{2} \neq 0.$$

Therefore, by the n -th term test, the series diverges.

Problem 9. Find the constant A so that

$$\sum_{k=2}^{\infty} A \left(\frac{2}{9} \right)^k = 5.$$

Answer:

This is a geometric series with ratio $r = \frac{2}{9}$. Thus, the series converges (since $|\frac{2}{9}| < 1$) and has the sum

$$\sum_{k=2}^{\infty} A \left(\frac{2}{9} \right)^k = \frac{A \left(\frac{2}{9} \right)^2}{1 - \frac{2}{9}} = \frac{\frac{4}{81}A}{\frac{7}{9}} = \frac{4}{63}A.$$

So, if

$$\sum_{k=2}^{\infty} A \left(\frac{2}{9} \right)^k = 5,$$

then we have

$$\frac{4}{63}A = 5 \Rightarrow A = \frac{315}{4}.$$
