

Introduction to ODE's

Def: An ordinary differential equation (ODE) is an equation involving a function $y = y(x)$, one or more of its derivatives, and x .

Ex: $y' - 2x = 0$

A solution is $y = x^2$. We can check it: $y' = 2x$ & so
 $2x - 2x = 0$.

We can also solve it by integrating:

$$y' = 2x$$

$$y = x^2 + C$$

In fact there are many solutions!

one for each value of C .

Ex $y' + 3y = 6x + 11$

A solution is

$$y = e^{-3x} + 2x + 3.$$

We verify it by differentiation:

$$y' = -3e^{-3x} + 2.$$

$$y' + 3y = 6x + 11$$

$$(-3e^{-3x} + 2) + 3(e^{-3x} + 2x + 3) = 6x + 11$$

$$2 + 6x + 9 = 6x + 11$$

$$6x + 11 = 6x + 11 \quad \checkmark$$

This ODE is more difficult to solve.

Ex $y'' - 3y' + 2y = 24e^{-2x}$

A solution is

$$y = 3e^x - 4e^{2x} + 2e^{-2x}.$$

$$y' = 3e^x - 8e^{2x} - 4e^{-2x}$$

$$y'' = 3e^x - 16e^{2x} + 8e^{-2x}$$

$$y'' - 3y' + 2y = (3e^x - 16e^{2x} + 8e^{-2x})$$

$$- 3(3e^x - 8e^{2x} - 4e^{-2x})$$

$$+ 2(3e^x - 4e^{2x} + 2e^{-2x})$$

$$= \underbrace{(3 - 9 + 6)}_{=0} e^x + \underbrace{(-16 + 24 - 8)}_{=0} e^{2x}$$

$$+ (8 + 12 + 4) e^{-2x}$$

$$= 24e^{-2x} \quad \checkmark$$

Def: The order of the ode
is the highest order derivative

of y that appears

Ex: (1) $y' - 2x = 0$ order 1.

(2) $y' + 3y = 6x + 11$ order 1

(3) $y'' - 3y' + 2y = 24e^{-2x}$ order 2

(4) $x^2 \boxed{y'''} + 3xy'' + xy' - 3y = \sin x$
order 3

(5) $\frac{4}{x} \boxed{y^{(4)}} + \frac{12}{x^2} y = x^3 + 4x$
order 4

Modeling.

- Population growth.

t = time

$P(t)$ = population at
time t

A reasonable model for the population growth of a population of bacteria/animals under ideal conditions

(unlimited environment, perfect nutrition, no predators, no diseases,)

is that the rate of growth is proportional to the population size:

$$\boxed{\frac{dP}{dt}(t) = \underbrace{k}_{\text{Constant}} P(t)}$$

Note:

If $k > 0$ then the population always grows. (Assuming $P(t) > 0$.)

We can in fact solve it!

$$\boxed{P(t) = Ce^{kt}}$$

Can check that this indeed solves the ODE: $P'(t) = k(Ce^{kt})$
 $= kP(t)$.

Any value of the const C gives a solution. Note

$$P(0) = Ce^{k \cdot 0} = C, \text{ so}$$

C = population at time 0

Graphs of some solutions for some values of C :

Of course we would not consider in our model because the initial population can not be negative.

More realistic model:

In less ideal situations, the amount of resources (e.g. food) are limited.

There's a "roof" or "carrying capacity" M such that

- $\frac{dP}{dt} \approx kP$ if P is small
- $\frac{dP}{dt} < 0$ if $P > M$

The logistic equation

$$\boxed{\frac{dP}{dt} = kP\left(1 - \frac{P}{M}\right)}$$

If P small compared to M
then $1 - \frac{P}{M} \approx 1$ so $\frac{dP}{dt} \approx kP$

If $P > M$ then $1 - \frac{P}{M} < 0$ so

assuming $k > 0$ we get

$$\frac{dP}{dt} < 0.$$

If $P \rightarrow M$ then $1 - \frac{P}{M} \rightarrow 0$

so $\frac{dP}{dt} \rightarrow 0$ meaning population
levels off as the population
reaches the carrying capacity.

There are two special solutions:

$$P(t) = 0 \text{ and } P(t) = M.$$

called equilibrium solutions.

These make sense: if population reaches 0 or M it stays at that size.

Motion of a spring:

Hooke's law: When a spring is stretched, the force it exerts on the weight is proportional

to the height.

$$\boxed{\text{Force} = -kx}$$

$$F = ma = m \frac{d^2x}{dt^2} = -kx$$

$$\boxed{x''(t) = -\frac{k}{m}x}$$

In fact a solution is

$$\boxed{x(t) = \sin\left(\sqrt{\frac{k}{m}}t\right)}$$
