Math 331, Fall 2002: Problems 7-10

NOTE: Each exercise is worth 10 points and can be turned in at any time before its "expiration date". At the end of the semester, I will expect you to have turned in at least 2/5 of the exercises assigned. If you do more, I will pick your best grades. If you do less, the missing grades will be counted as zeros. Altogether, these will count the same as one project.

- 7. (expires 9/30) Fit the points (-1.9, -4.7), (-0.8, 1.2), (0.1, 2.8), (1.4, -1.2), (1.8, -3.5) by means of a quadratic function $f(x) = ax^2 + bx + c$, using the least square method. First, do this step by step, as we did in class; then, use the built-in Maple command, described in the notes. Check that the two solutions agree.
- **8.** (expires 9/30) Fit the set of points

(1.02, -4.30), (1.00, -2.12), (0.99, 0.52), (1.03, 2.51), (1.00, 3.34), (1.02, 5.30)

with a line, using the least square method we used in class. You will see that this is not a good fit. Think of a better way to do the fit and use Maple to do it. Explain in your solution why you think your better way is better.

- **9.** (expires 10/7) [In this problem use Maple only as a word processor. If you're more confortable with paper, you can turn in a paper instead of a Maple worksheet.] Let n points of the form (r_i, r_i^2) , i = 1, 2, ..., n, be given. What is the quadratic function $f(x) = ax^2 + bx + c$ that best fits them? **Prove** your answer. Does it depend on the optimization method (least square or others)?
- 10. (*expires 10/7*) Once we have calculated the line (or any other curve, for that matter) that best fits a sets of points, we can get an idea how good the fit is by plotting the line together with the points. It is much more scientific, however, to have a measure for this. Come up with a function of the data and parameters of a given best-fit problem that is small when the fit is good and large when the fit is bad, no matter how many points are used. Justify your answer.
